THE

MEDICAL AND SURGICAL REPORTER:

A WEEKLY JOURNAL.

(ESTABLISHED IN 1858, BY S. W. BUTLER, M.D.)

EDITED BY

D. G. BRINTON, M.D.

AND

JOSEPH F. EDWARDS, M.D.

JULY–DECEMBER 1882.

120173

JAN 4 1883

SMITHSONIAN DEPOSIT.

VOL. XLVII.

PHILADELPHIA:
NO. 115 SOUTH SEVENTH STREET.
1882.

CONTRIBUTORS.

AGNEW, D. H., Clinic, 64.
ASHHURST, JOHN, Clinic, 596, 682.

BARKER, M. P., 679.
BARKER, M. R., 285.
BARNES, H. E. W., 502.
BART, D. M., 424.
BATTEN, JOHN M., 20,
BEACH, WILLIS J., 284.
BEATES, HENRY, Jr., 94.
BENNETT, E. H., 396.
BLACHEZ, M., 169.
BLACKWELL, E. T., 421, 725.
BOYLAND, GEO. H., 113, 143, 309, 592.
BRISAC-DREYFUS, M., 281, 533.
BROWN, C. H., 60.
BULLARD, A. M., 20.
BYRD, W. A., 428, 649.

CALDWELL, S. W., 298.
CARRELL, W. C., 76.
CARRIGAN, A. H., 341.
CARRIGAN, J. F., 419.
CHASE, HENRY S., 148.
CHAFEE, W. C., 697.
CHRISTINE, G. MAXWELL, 194.
CLARK, ALONZO, Clinic, 231, 512.
CROTHERS, T. D., 561, 620, 701.
CROTHERS, E. K., 726.

DICKINSON, S. W., 729.
DIEULAFOY, M., 57.
DOWDEN, W. H., 698.
DRAPER, W. H., Clinic, 371, 428, 569, 650.

EDWARDS, W. A., Report, 36, 400.
ENGEL, HUGO, 1, 171.
ESKRIDGE, J. T., 233.

FARNHAM, A. E., 643.
FARNSWORTH, P. J., 20.
FERNANDEZ, A. M., 511.
FERRO, CLAUDE M., 223.
FLINT, AUSTIN, Clinic, 286.
FOX, GEORGE H., Clinic, 262.
FOX, G. T., 530.

GASTON, J. M. F., 197, 227, 505, 673.
GETZ, H. L., 120, 261, 587.
GOODELL, WM., Clinic, 149, 203, 316, 540.
GREEN, TRAILL, 55.
GRIMES, J. H., 726.
GUSSENBAUER, C., Clinic, 730.

HEILMAN, J. G., 654.
HOPPEL, T. J., 343, 559.
HORNER, FRED, 225.
HOY, A. H., 418.
HUMPHREY, H. S., 299.

KEATING, JOHN M., Clinic, 1, 400.
KERSEY, V., 256.

LA FERTE, Prof., Clinic, 598.
LAUTENBACH, L. J., Report, 596, 682.
LEEDOM, O., 223.
LEVICK, A. T., 589.
LITTLE, W. S., Lecture, 449.
LITTLEFIELD, J. D., 75.
LONGAKER, D., 85.

McCANN, JAMES, Clinic, 542.
McCULLOCH, T. C., 251.
McEWAN, R. C., 88.
McKENNAN, T. M. T., Report, 542.
MAGNAN, M., 393.
MEIGS, A. V., 600.
MELSHEIMER, C. T., 419, 559, 707.
MERRICK, C. H., 147.
MICHENER, E., 704.
MILLER, C. H., 278.
MORRISON, W. H., Report, 64, 90, 149, 203, 316, 540, 625, 708.
MUHLENBERG, W. F., 49.

NIGHTINGALE, H. B., Report, 681.
NYE, H., 167, 670.

OTIS, FESSENDEN N., Clinic, 177.

PEPPER, WM., Clinic, 90, 625, 708.
POWELL, W. B., 332, 427.
POWELL, H. R., 698.

RECLUS, M. P., 645.
REESE, JOHN J., 28.
REYNOLDS, D. S., Clinic, 457.
ROSENTHAL, EDWIN, 122.
RUSH, G. G., 111.

SAVAGE, G. C., 117, 483.
SCHULTZ, S. S., 259.
SCHWARTZ, L., Report, 730.
SEELYE, H. H., Report, 371, 428, 569, 650.
SHEARER, JAMES Y., 257.
SHIMONEK, F., 557.
SHIPPS, W. H., 481.
SHOEMAKER, J. V., Clinic, 122.
SHULL, E. H., 193.
SHUGERT, F. A., 669.
SIBBETT, R. L., 196, 475.
SMITH, JOHN S., 453.
SMITH, T. CURTIS, 34, 141, 201, 314, 337, 564.
SOUWERS, GEO. F., Report, 449.
SOZINSKEY, T. S., 194, 253, 477.
SPANGLER, CHAS. F., 260.
STILLMAN, W. O., 29, 279.
STUBBS JOSEPH, 32.
SUNDBERG, J. C., 390.
SWERINGEN, H. V., 4.

TAYLOR, FRED A., Report, 6.
THAYER, C. C., 365.
TURNBULL, CHARLES S., Report, 189, 274, 471, 638, 720, 735.
TURNBULL, L., 426, 539.

UPDEGRAFF, Thad. S., 174.

VANDERPOEL, E., 559.
VALENTINE, F. C., 397, 617.

WALLACE, ELLERSLIE, 736.
WARREN, J. H., 368, 648.
WEIR F. LE S., Clinic, 681.
WELCH, H. G., 121.
WIGHT, J. S., 538, 624.
WILSON, H. A., 543.
WITTKAMP, ANDREW L., 111.
WOODSON, T. M., 419.

YARROW, H. C., 536.
YANDELL, L. P., 670.
YOST, GEO. P., 367.

INDEX.

Abdomen, incised wound of, 511.
Abdominal; cavity, partial escape of fœtus into the, 39; tumor, probably ovarian, 540.
Abnormally long processus styloideus, 501.
Abortion; self, 299; butternut as a preventive remedy in, 330, 418; to prevent necessity for inducing, 529.
Abortive gonorrhœa, treatment of, 413, 638.
Abscess; of the pharynx, 65; hydronephrosis, 383; hepatic, traumatic injuries of, 516.
Abscesses; practical conclusions with reference to, 592; pyæmic, of lungs, 684; of the liver, 684.
Absorption by the skin, 696.
Abuse of injections of morphia, 518.
Abuses, emigrant, 72.
Acid; *boracic*, for granular lids, 104; *carbolic*; in typhoid fever, 133; in blood poisoning, 189; for carbuncles, 386; and carbolates, 712; *hydrobromic*, 106; *pyrogallic*, in venereal ulcers, 604; *salicylic*; as a remedy for corns, 55; in typhoid fever, 492, 529; *sclerotinic*, 321; *sulphurous*, in typhoid fever, 215; in consumption, 612; *tannic*; in albuminuria, 136; administration of, 160; topical uses of, 389.
Accidents, surgical, in the insane, 407.
Acne, 681.
Aconite; 528; and digitalis, 297; in dysentery, 414; hydrophobia cured by, 502.
Action; of hot foot baths, 575; of kava, 585.
Actions of pepsin, 555.
Actual cautery for dermato-cellulitis, 557.
Acute; rheumatism, hyperpyrexia in, 127; endocarditis, 138; articular rheumatism, sulphate of soda in, 141; myelitis, with double-sided neuritis optici, 187; hydrocephalus, 260; peritonitis, 284; rheumatism and salicylate of sodium, 297; salicylates in, 367; chorea, treatment of by massage, 432; conjunctivitis, caused by electric lights, 442; laryngitis, turpeth mineral in, 557; heart lesions in the very old, 612; urethritis, treatment of, 648.
Addison's disease, 152.
Adenitis, cervical, 345.
Adenoma, 313.
Adenomata, mammary; do they undergo carcinomatous degeneration? 94.
Administering tannin, 19.
Administration; of tannic acid, 160; of ether, 209, 278.
Adipose tissue, trichinæ in, 555.
Adolescence, cephalalgia of, 733.
Advantages of country life to literary men, 466.
After pains, salicine for, 387.
Ages, the dark and light, 326.
Ague; brow, 70; willow leaves in, 245.
Air; azonized as a hypnotic, 135; sanitary features of the humidity of heated, 477.
Albumen; retractile, 11; in urine, new test for, 657; new reaction for, 668.
Albuminuria; 533; tannic acid in, 136; significance of, 180, 551; transient, 586; clinical observations on, 600.
Alcohol; and syphilis, 272; inhalations in croupal diphtheria, 707.
Alimentation; forced, in phthisis, 74; artificial, in nervous vomiting, 214.
Aliments and medicines introduced through the nasal cavity, 171.
Aloetic pills, 124.
Amaurosis, quinine, in one eye, 274.
American; dyspepsia, 294; academy of medicine, 530; vs. European profession, 693.
Ammoniated mercurial peptones, 215.
Amputation; of the vaginal portion of the trigeminus, neuralgia caused by, 217; of both legs, without ligatures, 577; at the hip-joint, 647.
Amputations; statistics of, 321.
Amussat's operation for imperforate rectum, Verneuil's modification of, 649.
Amyl nitrite; in hour-glass contraction of uterus, 44; hypodermic use of, 100; chloroform and, 415.
Amyloid kidney, 319.
Anæsthetics in diseases of kidneys, 426.
Anchylosis of joints, 348.
Anecdote of Jenner, 672.
Anencephalic monster, 461.
Aneurism; mitral, 108; of axillary artery, 256; of carotid, 489.
Angina; Ludwig's, case of, 97; pectoris, treatment of, 385, 414, 612.
Ankle, sprain of, 653.
Anosmia, 215.
Antagonism between strychnia and opium, 188.
Ante partum, hour-glass contractions, 669.
Anterior chamber of eye, eyelashes in, 695.
Antiseptic; treatment of wounds, the position of iodoform in, 184; inhalations in the treatment of lung cavities, 218; a new, 412.
Antiseptics, value of, 666.
Antipyretic, cinchonidia as an, 192.
Anti-scorbutic, a new, 613.
Anti vivisection, absurdity of, 488.
Anus, fissure of, 17.
Apomorphia; as an expectorant, 188; use of, 491; as an emetic, 667.
Apoplexy, 431.
Apparatus; for the administration of ether, 209; for the treatment of pelvic cellulitis, 718.
Appendix vermiformis, removal of, from a hernia sac 547.
Application to corns, 273.
Appropriate reference, 223.
Appropriation for the prevention of epidemics, 269.
Arms, compound fracture of both, 244.
Arnica tincture, improvement on, 441.
Arsenic and the secretion of milk, 186.
Arsenical poisoning, dialysed iron in, 19.
Artery; axillary, aneurism of, 256; innominate, ligature of the, 328; popliteal, laceration of, 543; pulmonary, dilatation and atheroma of, 687.
Arthritis, fungous, treatment of, 208.
Artificial; alimentation in nervous vomiting, 214; food for infants, 699.

Ascites in children, 159.
Aseptic needle forceps, 428.
Aspiration; of the bladder, 698; of the chest, 699.
Asses' milk, 442.
Association of medical officers of American institutions for idiotic and feeble minded persons, 447.
Asthma and bronchitis, diet in, 48.
Asthmatic; attacks, nasal polypi and, 217; antimixture, 414.
Ataxia, locomotor; peculiar attacks in, 295; of syphilitic origin, 355; lesions of the teeth in, 690.
Atelectasis pulmonary, 402.
Athetosis and vaso-motor neuroses of the extremities, 187.
Athletic Association of the University of Pennsylvania, 615.
Athrepsia, treatment of, 552.
Atrophic kidney, 14.
Atropia; salts, hypodermic injection of the, 463; for dribbling from the mouth, 471.
Atropine as a cause of glaucoma, 387.
Autopsy of a case of transposition of the viscera, 543.
Axillary; glands, removal of, 42; artery, aneurism of, 256.

Bacilli tubercle, easy method to discover, 636.
Bacillus tuberculosis, how to detect for diagnosis, 467.
Bacteria; growth of, 49; of typhoid fever, 462; and chronic dysentery, 580; the latest about, 609.
Bait for ambitious investigators, 390.
Banquet at Little Rock, 27.
Base of skull, fracture of, 542.
Baths; electrical, 29, 279; hot-foot, action of, 575; prolonged employment of in therapeutics, 660.
Bean, the sooy, 556.
Belladonna; poisoning, 76; and atropia, medical and surgical uses of, 463; vs. opium, 726.
Berlin hygienic exhibition, 28.
Bilateral herpes zoster, 502.
Biliary calculus, 536.
Billroth, on removal of cancer, 18.
Biological, experimental researches, 290.
Birth, quadruple, 556.
Bismuth; in dyspepsia of children, 529; subnitrate, for cancrum oris, 638.
Bladder; new way to detect stone in the, 243; stone in the, 419; partial resection of, 583.
Blepharitis, 61.
Blind, stenography for the, 470.
Blisters; the employment of, on children, 554; treatment of rheumatism by, 732.
Blue marks and pediculi, 586.
Blood; corpuscles, staining of nucleated, 104; dried, 216; successful transfusion of, 405; poisoning, carbolic acid in, 419; diet, 553.
Bodies, foreign, swallowed, 690.
Boiled milk, in summer complaints, 273.
Bone; sequestrum, 346; gummata, 500; marrow and spleen, function of, 500.
Bones of the skull, displacement of, 501.
Book reviews, 439.
Boracic acid, for granular lids, 104.
Boracis glycerinum, for chancres, 15.
Borax; in epilepsy, 717; or boracic acid in diphtheria, 712.
Boro-glyceride, 719.
Bovine vs. human virus, 725.
Bowel, sloughing of, 637.
Boys, the use of tobacco by, 437.
Brain; tumor; with eye symptoms, 160; two cases of, 187; of the cortical substance of, 297; gunshot wound of, 268; syphilis, 637; lesion, remarkable case of, 667.
Breast, scirrhus of, 683.
Bright's disease; 231, 485, 570; certain accidents of; 57; pathology and treatment of, 225; inheritance and hygiene of, 412; fuchsine in, 416; pilocarpia in, 580, 668.
British Medical Association, 299.
Broken neck, recovery after, 719.
Bromide of potassium in diabetes, 286.
Bromo-menorrhœa, 666.
Bronchitis and asthma, diet in, 48.
Brow ague, 70.
Brucia, poisoning with, 194.
Bullets, piosonous, 442.
Bursting pelvic cyst, 599.
Butternut as a preventive remedy in abortion, 330, 418.
Buttocks, furunculosis of, 7.

Caffein, hypodermic injections of, 188.
Calculous pyelitis, 627.
Calculus; disintegrated hepatic, 75; renal, 92; biliary, 536.
Calomel, serious effects upon the eye, 471.
Cancer; Billroth on removal of, 18; vs. syphilis, 162; excision of pylorus for, 265; of the vagina, 541; of the pylorus, 559; of stomach, 625.
Cancrum oris, subnitrate of bismuth for, 638.
Can dreams be controlled, 84.
Canning establishments, sanitary precautions for, 280.
Capitis pediculi, 667.
Caput obstipum, 527.
Carbolic; acid; in typhoid fever, 133; in blood poisoning, 189, 419; for carbuncles, 386; for nævi, 414; and salicylic acids, 389; spray, a proposed substitute for, 526; and carbolates, 712.
Carbonic oxide, glycosuria in cases of poisoning by 245.
Carbuncles, carbolic acid for, 386.
Carcinoma; of the stomach, 222, 404; mammæ, 403; primary, of pancreas and liver, 630.
Carcinomatous; degeneration, do mammary adenomata undergo? 94; large intestine, resection of, 375.
Card from Prof. John J. Reese, 28.
Cardiac; murmurs, in the puerperal state, 137; disease, temperature in, 295; inhibition, the influence of blood pressure on, 501; affections, with neuralgia of left arm, 632; form of typhoid fever, 694.
Care of the teeth, 72.
Carious tooth, hemorrhage and gangrene from, 15.
Carlyle's patience, 615.
Carotid, aneurism of, 489.
Cartilage; arytenoid, expulsion of, 27; thyroid, fracture of, 105.
Case; a singular, 56; of complete madarosis of

the upper lids, 63; of typhoid fever, 66, 421; of Ludwig's angina, 97; of pustular syphiloderma simulating smallpox, with its treatment, 122; of poisoning by brucia, 194; from whiskey, 615; of transverse fracture, without separation of fragments, 202; of acute hydrocephalus, 260; of quinine amaurosis in one eye, 274; of acute peritonitis, 284; of strangulated hernia, 396; of carcinoma mammæ, 403; of tetanus, 427; of early puberty, 492; of fistula of the pancreas, 499; of transposition of the viscera, 543; of labor, 642; a peculiar, 644; remarkable, of brain lesion, 667; of elephantiasis græcorum, 685; of septicæmia 697; of incarcerated hernia, 699; rare, in practice, 726.
Caseous, degeneration of the kidneys, 572.
Cases; report of typhoid, 34; of hydrophthalmus treated with iridectomy, 274; of juvenile convulsions, 589; of albuminuria, 600.
Casts and models, new material for, 633.
Catarrh, rational treatment of, 667.
Catarrhal fever, recent epidemic in Philadelphia of, 171.
Catching cold from wettings with salt water, 413.
Cause of tetanus, 613.
Causes; of labor before and at term, 110; of malaria, 139; of sudden death, 411.
Caution about a popular toothache remedy, 645.
Cavities, serous, chyliform effusions into, 281.
Cellulitis, pelvic, treatment of, 718.
Centre, the respiratory, 499.
Cephalalgia of adolescence, 733.
Cerebral; meningitis, chronic 97; centre for the color sense, 354; disease, misleading symptoms of serious, 585.
Cerebrum, the effects of certain remedies on the irritability of the, 237.
Central American medical curiosities, 397, 617.
Certificates in sanitary science, 614.
Cervical; adenitis, 345; vertebra, sub-luxation of fourth, 407.
Cervix uteri; nitrate of lead in cancer of, 106; laceration of, 729.
Chair of operative surgery in Berlin, 419.
Chancre, syphilitic infection from an oral, 69.
Chancres, glycerinum boracis for, 15.
Changes in the secretion of milk under influence of medicines, 581.
Charbonneux vaccin, 587.
Chas. Darwin, memorial, 179.
Chest; in hydatid cyst of the lung opening of, 216; aspiration of, 699.
Chicory, a new source of alcohol, 560.
Children; night terrors of, 90; ascites in, 159; cod-liver oil in young, 221; bismuth in dyspepsia of, 529; colic in, 632.
Childhood, tertiary syphilis in, 271.
Chinoidine, 389.
Chloral hydrate, therapeutics of, 469.
Chlorate of potash and tincture of iron in scarlet fever, 695.
Chloride of potassium, a common mistake concerning, 216.
Chloroform; death from, 84; and salicylate of soda in the treatment of uræmic convulsions, 106; as an adjuvant to morphia hypodermically, 106; vs. ether, 151; inhalation of, 158; and nitrite of amyl, 415; in labor, prolonged use of, 441; and morphia narcosis, 555.
Cholera; 636; epidemic, the threatened, 352; infantum, rumors, 532; resorcin in, 600; -like symptoms in uræmia, 666.
Chlorodyne to control diarrhœa, 556.
Chorea, hydrate of choral in, 386.
Chronic; eczema rubrum, of leg, 7; metritis, treatment of, 17; cerebral meningitis, 97; dysentery, koroniko in, 218; inflammation of the ovary, 318; dysentery and bacteria, 580; parenchymatous nephritis, 631; chyliform effusions into serous cavities, 281.
Cinchonidia as an antipyretic, 192.
Cirrhosis of liver in the stage of enlargement, 573.
Clinical; thermometers, 161; study of inebriety, 561, 620, 701; experience at the obstetric bedside, 314; observations on albuminuria, 600.
Close of the year, 733.
Clubfoot, treatment of, 653.
Coca, to assuage thirst, 385.
Code, New York, 88.
Codeia in diabetes, 106.
Cod-liver oil in young children, 221.
Coffee and its effects, 526.
Cold treatment of scarlatina, 257.
Colic; hepatic, 536; in children, 632.
Colleges, medical, a meditation on, 410.
Colon, stricture at the sigmoid flexure of the, 147.
Color sense, cerebral centre for, 354.
Coma during menstruation relieved by venesection 719.
Comedones, pomade for, 415.
Communications, confidential, to physicians, 130.
Comparative size of drops, 252.
Compendium, Quarterly, of Medical Science, 498.
Complete lateral dislocation of the elbow joint, 223.
Compound fracture of both arms, 244.
Concealed uterine hemorrhage, 8.
Conclusions, practical, with reference to abscesses, 592.
Conduction in patella reflex, the rapidity of, 132.
Confidential communications to physicians, 130.
Congenital; cardiac disease, 137; occlusion of the rectum, 502; absence of kidney, 718.
Congestive affections of the throat, 26.
Conjugal onanism, 670.
Conjunctiva, on croup of the, 189.
Conjunctival inflammation, contagious forms of, 189.
Conjunctivitis, diphtheritic, treated with quinine, 73.
Conscienceless physician, 639.
Constitutional diatheses, their influence on traumatic lesions, 645.
Consumption; laryngeal complications of; 289; contagiousness of, 381; some observations on, 382; sulphurous acid in, 613.
Contagious; ophthalmia, 189; diseases, isolation in, 328.
Contagiousness of pulmonary consumption, 381.
Contagium vivum malariæ. 74.
Contracted finger; treatment of, 585.
Contraction, hour-glass, of uterus, nitrite of amyl in, 44.
Contribution to the peripheral temperature of the human body, 352.

Convallarine, 388.
Convulsions; uræmic, and coma, treatment for, 105; pilocarpin in uræmic; 219; puerperal, veratrum viride in, 332; infantile, nitrite of amyl in, 386; two interesting cases of juvenile, 589.
Corns; salicylic acid as a remedy for, 55; application to, 273.
Coronary artery, rupture of, 138.
Corpus luteum, 16.
Corpuscles, staining of nucleated blood, 103.
Correction, a, 736.
Cortical substance of the brain, tumor in, 297.
Counter irritation, 347, 380.
Country life, the advantages of to literary men, 466.
Cowpox, a query about, 586.
Cradle of American medicine, 559.
Criminal women, health of, 610.
Cranial osteophytes, 162.
Cramp; writers', 576; treatment of, 584.
Cranii paracentesis in hydrocephalus, 182.
Craniology of murderers, 353.
Cremation; 643; in France, 308, 671.
Croup; of the conjunctiva, 189; turpeth mineral in, 582.
Croupal diphtheria, inhalations of alcohol in, 707.
Crural neuralgia among dentists, 376.
Curare; in epilepsy, 355; in treatment of hydrophobia, 582.
Curiosities, medical, of Central America, 397.

Inspectors, sanitary, 270.
Instruction, post-graduate, in Philadelphia, 549.
Instrument; for the reduction of flexions of the womb, 120; new, 174.
Instruments, surgical, 245.
Interesting case of juvenile convulsions, 589.
Intermarriage, effects of, 196.
Interconvertibility of zymotic diseases, 546.
Intercondyloid fracture of femur, 543.
International; medical congress, 1876, 54; hygienic convention, 475.
Interstitial fœtation, 658.
Intestinal obstruction relieved by puncture of bowel, 381.
Intestine; resection of carcinomatous large, 375; incised wound of the abdomen, with prolapsus of, 511; small spindle-celled sarcoma of, 630.
Intra-uterine fibroid, removal of, 174.
Intravenous injection of fluid for hemorrhage, 574.
Introduction of aliments and medicines through the nasal cavity, 161.
Intussusception; with recovery, 182; in infants, 440.
Invalids, rides for, 643.
Investigators, bait for ambitious, 390.
Iodide of potassium; death probably produced by, 557; action of, 698
Iodine; spina bifida cured by injections of, 47; tincture in erysipelas, 388.
Iodoform; in the antiseptic treatment of wounds, 184; to mucous surfaces, 188; dressing in Vienna, 206; poisonous effects of, 349; in syphilis, hypodermic injection of, 354; in tuberculous pharyngitis, 355; in phthisis, 387; in diabetes, 390; in syphilis, 470.
Irreducible hernia, new treatment of, 272.
Irritation, counter, 347, 380.
Irritability of the cerebrum, effects of certain remedies on the, 237.
Iron; in the urine, 356; tincture, and chlorate of potash in scarlet fever, 695.
Isolation; in the Paris Maternite, 216; in contagious diseases, 328.
Italy, ovariotomy in, 694.

Jaborandi in typhoid fever, 218.
Jaundice with hydatids of the liver, 136.
Jaw, dental tumor of, 17.
Juvenile convulsions, cases of, 589.
Joints, anchylosis of, 348.

Journals, spurious medical, 524.
Journalism, one of the difficulties of, 466.

Kava, action of, 585
Keratin, a purer, 185.
Kidney; atrophic, 14; amyloid, 319; and pelvis, severe injury to, 714; congenital absence of, 718.
Kidneys; anæsthetics in diseases of, 426; myotic disease of, 555; caseous degeneration of, 572.
Klein on vaccine charbonneux, 531.
Knee, re-excision of, 682.
Kolplokleisis for vesico-vaginal fistula, 441.
Koroniko in chronic dysentery, 218.

Labor; steatomatous tumor obstructing, 75; cause of, before and at term, 110; prolonged use of chloroform in, 441; tedious case of, 642.
Labors, troublesome, 406; made tedious by rigidity of soft parts, 725.
Laceration; of the female perineum, 4, 424; of popliteal artery, 543; of cervlx uteri, 729.
Lachrymal gland, tumor of, 473.
Lancet in dentition, 253.
Laryngeal; complications of consumption, 289; phthisis, 371.
Laryngitis, acute, turpeth mineral in, 557.
Last scene of a sad history, 129.
Latest about bacteria, 609.
Lawn tennis arm, 552.
Laws of inheritance, 575.
Lead paralysis, from contact, 440.
Lectures, new century, 699.
Leg; vesicular eczema of, 6; ulcer of, 347.
Legacy to the French government, 111.
Legislation; medical, 475; for the prevention of syphilis, 157.
Legs, amputation of, without use of ligatures, 577.
Lehigh Valley Medical Association, 279.
Leprosy, inoculation of, 75.
Lesion; brain, remarkable case of, 667; of the teeth in locomotor ataxy, 690.
Lesions; of the phrenic nerves, 493; of the brain, lung, heart, liver, spleen, kidney and bladder, 629; traumatic, influence of constitutional diathesis on, 645.
Library, Toner medical, 139.
Lichen ruber, cure of, without arsenic, 388.
Lids, boracic acid for granular, 104.
Life, the secret of a noble, 614.
Ligation of pedicle around drainage tube in extirpation of the womb, 505.
Ligature; wire, for divided bones, 272; of the innominate artery, 328; elastic, for opening sinues, 329.
Ligatures, amputation of both legs without use of, 577; best material for, 719.
Light, influence of, on vision, 441.
Lime water, with milk, long continued use of, 244.
Lipoma, treatment of, 311.
Literary; act, discreditable, 138; men, advantages of country life to, 466.
Liver; jaundice, with hydatids of, 136; traumatic injuries of, 516; ferruginous, 529; hydatid cysts of, 543; scirrhosis of, 573; rupture of, 585; and pancreas, primary carcinoma of, 630; abscess of, 684; with metastases, 689.
Local treatment of erysipelas, 613.
Locomotor ataxia; skin eruptions in, 214; peculiar attacks in, 295; of syphilitic origin, 355; lesions of the teeth in, 690.
Look out for smallpox, 610.
Ludwig's angina, case of, 97.
Lung, opening of the chest in hydatid cyst of the, 216.
Lupus, micrococci of, 217.
Lymphatic, pseudo-leucæmia, 708.
Lymphomatous tumor of mediastinum, 572.

Madarosis of the upper lid, 63.
Maggots in fæces, 719.
Malaria; cause of, 139; and pharmacy, 503; in skin diseases, 669.
Malariæ contagium vivum, 74.
Malate, ferrous, solution of, 530.
Malignant pustule, 154.
Malpractice, Medical, 716.
Mammary adenomata, do they undergo carcinomatous degeneration? 94.
Mammæ carcinoma, 403.
Manipulation in urethritis, 648.
Manner of administering tannin, 19.
Manufacture of dynamite, 692.
Marks, blue, and pediculi, 586.
Marsh fever in Athens, 715.
Marvel of surgery, 297.
Massage, treatment of acute chorea by, 432.
Masturbation and sexual excesses, cause of eye diseases, 296.
Maxilla, superior, exanthematous necrosis of 453.
Maxillary, excision of superior, for neuralgia, 519.
Measles; the recent epidemic of 233, 727; pathology, of, 584.
Meat; fresh, scurvy and, 433; digestion of, 607.
Mecca, water of the sacred springs at, 16.
Mediastinum, lymphomatous tumor of, 572.
Medical; congress, international, 1876, inception of, 54; statistics in Cleveland, Ohio, 109; experts, 84, 271; and surgical supplies on railroad trains, 193; practitioners, registration of in Pennsylvania, 194; and surgical practice, the innovations of, 197, 227; service in the British army, 357; centre, Prague as a, 307; legislation, 378, 475; and sanitary national exhibition, 385; curiosities of Central America, 397, 617; and surgical uses of belladonna and atropia, 463; teaching, fallacies in, 495; education, the problem of, 521; museum and library, action of Philadelphia County Medical Society, 559; missions in heathen lands, 679; malpractice, 716.
Medical Societies—
American Dermatological Association, 363.
American Academy of Medicine, 530.
American Gynecological Society, 442.
American Laryngological Association, 20.
American Medical Association, 76.
British Medical Association, 332, 356.
Canada Medical Association, 445.
College of Physicians, Philadelphia, 543, 600.
Lebanon County Medical Society, 615.
Lehigh Valley Medical Association, 279.
Massachusetts State Medical Society, 55.
Northern Medical Association of Philadelphia, 66, 94, 654.
Obstetrical Society of Philadelphia, 39, 458.
Pathological Society of Philadelphia, 403, 571, 629, 683.

Philadelphia Laryngological Society, 97.
Tri-State Medical Society, 307.
Transactions of the Obstetrical Society of Philadelphia, 599.
Medicated soaps, 560.
Medication, fœtal, 337.
Medicine; regular, 111; neuro-dynamic, 290; the revival of, 299; a science?, 341; the cradle of American, 559; influence of, in the secretion of milk, 581; in England, beginning of this century, 613; modern, great characteristic of, 643; scientific position of, 663.
Meditation on medical colleges, 410.
Melanotic sarcoma of orbit, with metastases of liver, 689.
Memorial, Chas. Darwin, 179.
Menorrhœa-bromo, 666.
Meningitis, chronic cerebral, 97.
Menorrhagia, treatment of. 490.
Menstruation; painful, 329; during coma relieved by venesection, 719.
Mental activity and tissue metamorphosis, 528.
Mercurial; peptones, ammoniated, 215; poisoning, 734.
Mercury, a peculiar idiosyncracy as to, 239.
Metritis, chronic, 17.
Micrococci; of lupus, 217; vaccinal, 613.
Micro-germs, 49.
Microscopical examination, 42.
Midwifery in the Sandwich Islands, 390.
Milk; sickness, 168; arsenic and secretion of, 186; long continued use of lime water with, 244; asses', 442: powder in gastric affections, 527; influence of medicines in the secretions of, 581.
Miners' nystagmus, 697.
Mineral, turpeth, in croup, 582.
Meniere's disease, 330.
Misleading symptoms of serious cerebral disease, 584.
Mistake, poisoned by, 616.
Mistaken diagnosis, 111.
Mitral aneurism, 108.
Mixed chloroform, 555.
Morphia narcosis, 555.
Models and casts, new material for, 632.
Modification, proposed, of Esmarch's method, 554.
Molecules, physiological activity of super-oxidized, 206.
Monster, anencephalic, 461.
Monstrosities, fœtal diagnosis of, 611.
Monstrosity, a two-headed, 154.
Morbilli; and rötheln, 37; scarlatina, 499.
Morgagni, hydatid of, 459.
Morphia; hypodermically, as an adjuvant to chloroform, 166; death from, without narcotism, 167; and apomorphia, 491; abuse of injections of, 518; poisoning, 553; narcosis, mixed chloroform. 555; sulphate, sixteen grains at one time, 697.
Morphiomania, 492.
Mortality; in heated terms, 184; of black and white troops, 391.
Mouth, tapeworm passed by, 734.
Mucous; patch, 7; surfaces, iodoform to, 188; membrane of stomach, ecchymosis of, 631.
Multiple; sarcomata, 125; myoma of the neck of the uterus, 469.
Mumps, with endocardial murmurs, 138.
Murderers, craniology of, 353.
Muscarin, the effects of, 556.
Muscle, transplantation of, in human beings, 668.
Muscles, affections of the external ocular, 449.
Muscular, nuclear, paralysis of the eyes, 295.
Museum, proposed sanitary, in Sunderland, 615.
Mutilation, self, 48.
Mycotic disease of the kidneys, 555.
Mydriatic, a new, 217.
Myelitis, acute, with double-sided neuritis optici, 187.
Myo-fibromatous tumor, removal of, 111.
Myrabolans emblic, 387.
Myxomatous tumor of posterior cervical region, 629.

Nævi, carbolic acid for, 414.
Narcotism; in infancy, 153; death from morphine without, 167.
Nasal cavity; introduction of aliments and medicine through the, 161; polypi and asthmatic attacks, 217.
National Board of Health; and Congress, 323; report, 670.
Nature's removal of a tumor, 555.
Naval museum of hygiene, 448.
Neck; of femur, ununited fracture of, 65; transfixion of, by a walking stick, 180; broken, recovery after, 719.
Necrosis; of the tibia, 64; of the femur, 65; exanthematous, of the superior maxilla, 453.
Needle manufacturers, phthisis among, 133.
Neglect of the study of pure science in America, 293.
Neonatorum ophthalmia; treatment of, 135; tetanus, 181.
Nephrotomy; 612; for strumous disease of kidney, 354; and nephrectomy, for pyelitis, 605.
Nephritis; scarlatinal, tardy development of, 576; parenchymatous, chronic, 631.
Nerve stretching; 440, 552, 734; physics of, 43; sciatica cured by, 244; subcutaneous, 189.
Nerves; divided, restoration of, 345; vaso-constrictor, 462; phrenic, lesions of, 493.
Nervous vomiting, artificial alimentation in, 214.
Neuralgia; 47; of trigeminus cured by amputation of the vaginal portion, 217; crural, among dentists, 376; excision of superior maxillary and inferior dental nerves for, 519; of left arm, with cardiac affections, 632; decolorization of hair, with, 717.
Neuritis optici, double-sided, acute myelitis with, 187.
Neuro dynamic medicine, 290.
New; alkaloid, erythrophlëin a, 296; anatomical truss in treatment of rupture, 368; anti-scorbutic, 613; antiseptic, 412; born child, vaginal hemorrhage in a, 162; form of splint for fracture of the patella, 201; Grecian pharmacopœia, 419; instrument, 174; method of treating uterine hemorrhage, 285; mydriatic, 217; remedy for spasms, 468; treatment of irreducible hernias, 272; way to detect stone in the bladder, 243; material for casts and models, 633; century lectures, 699; reaction for albumen, 668; sign of pregnancy, 667; test for albumen in urine, 657.
New York code, 88.
Night terrors of children, 90, 384.

Nitrate; of lead in cancer of cervix uteri, 106; of sodium in epilepsy, 134.
Nitrite; of amyl, in hour glass contraction of uterus, 44; in infantile convulsions, 358; and chloroform, 415.
Noble life, secret of a, 614.
Nodes, rheumatic, 718.
Nose, tubercular syphiloderm of, 6.
Noteworthy example, 727.
Nuclear muscular paralysis of the eyes, 295.
Nucleated blood corpuscles, differential staining of, 103.
Nuisances, 609; public, 615.
Numerous progeny, 613.
Nurses, training schools for, 636.
Nystagmus, miners', 697.

Surgical; and medical supplies on railroad trains, 193; instruments, 245, 251; accidents in the insane, 407.
Suture of tendon, 331.
Swallowed, foreign bodies, 690.
Sweating; sickness of the sixteenth century, 28; excessive, treatment of, 415.
Sycosis, treatment of, 19.
Sydenham, 503.
Sympathetic inflammation, pathology of, 638.
Symptoms; misleading, of serious cerebral disease, 584; cholera-like, in uræmia, 666.
Synovial sheaths of tendons, tubercle of, 348.
Syphilis; the initial lesion of, 126; legislation for the prevention of, 157; vs. cancer, 162; association of tabes dorsalis with, 164; treatment of, 165; therapeutics of infantile, hereditary, 219; tertiary, in childhood, 271; and alcohol, 272; deaths of children from; 330; hypodermic injection of iodoform in, 354; disguised, 379, 564; conveyed by skin-grafts, 382; ocular, cyanide of mercury in, 387; iodoform in, 470; Egyptian treatment of, 503; brain, 637; respirator in, 637.
Syphilitic; infection from an oral chancre, 69; periostitis, 124; pachymeningitis of cerebellar fossa, 162; paralysis, 163; deformity of the teeth, 163; diathesis, 400; reinfection of husband and wife, 409.
Syphiloderma, pustular, simulating smallpox, 122.
Syringe, hypodermic, 1.

Tabes dorsalis, association of with syphilis, 164.
Tablets, danger from toy paint, 18.
Tack in the ear, 718.
Tænia solium, turpentine for, 468.
Tannic acid; in albuminuria, 136; administration of, 160; topical uses of, 389.
Tannin, manner of administering, 19.
Tapeworm; pelletierine for, 388; rational treatment of, 418.
Tardy; wisdom, 242; development of scarlatinal nephritis, 576.
Tea, preparation of, 700.
Teaching, medical fallacies in, 495.
Tedious case of labor, 642.
Teeth; care of, 72; syphilitic deformity of, 163; lesions of, in locomotor ataxy, 690.
Telangiectasis, treatment of, 313.
Temperature; in cardiac disease, 295; and pulse, influence of tobacco smoking on, 434; in early stages of phthisis, 661.
Tendon; suture of, 331; and other reflexes, 554.
Tendons, tubercle of the synovial sheaths of, 348.
Tennis, lawn, 552.
Tertiary syphilis in childhood, 271.
Terrors, night, in children, 90, 384.
Testes in perineo, 546.
Testicle, removal of a tuberculous, 121.
Tetanus; neonatorum, 181; a case of, 427; traumatic, recovery from, 460; therapeutics of, 469; cause of, 613.
Therapeutic; agent, static electricity as a, 209; properties of quinia, iodate and bromate, 222; progress, 218, 386; employment of prolonged baths, 660.
Therapeutics; of infantile hereditary syphilis, 219; and physiology, 468; of chloral hydrate, 469; of tetanus, 469.
Thermometers, clinical, 161.
Thigh; spindle-celled sarcoma of, 404; stump, painful scar removed from, 624.
Thirst, coca to assuage, 385.
Thought, the speed of, 518.
Threatened with typhoid, 498.
Throat, congestive affections of, 26.
Thymol and ether in chronic ringworm of the scalp, 221.
Thyroid cartilage, fracture of, 105.
Thyrotomy, 27.
Tibia, necrosis of, 64.
Tincture; of iodine in erysipelas, 388; of arnica, improvement on, 441.
Tinea tonsurans, epidemic of, 18.
Tissue; metamorphosis and mental activity, 528; trichinæ in adipose, 555.
Tobacco; smoking, its influence on temperature and pulse, 434; the use of, by boys, 437.
Toner medical library, 139.
Tongue; excision of, 469; tuberculosis on, 528; and larynx from case of elephantiasis græcorum, 685.
Tonsillotomy and hemorrhage, 500.
Tooth, paralysis after extraction of, 217.
Toothache remedy, caution about, 695.
Touts or examiners—query, 439.
Toy paint tablets, danger from, 18.
Trachea; supposed foreign body in, 66; traumatic stenosis of, 696.
Tracheotomy, 135.
Training schools for nurses, 636.
Transfixion of neck by a walking stick, 180.
Transfusion of blood, 405.
Transient albuminuria, 586.
Transplantation of muscles in human beings, 668.
Transplanted flap, painful scar covered by, 624.
Transposition of the viscera, autopsy of, 543.
Transverse fracture without separation of fragments, 202.
Traumatic; tetanus, recovery from, 460; ophthalmoplegia, 502; injuries of liver and hepatic abscess, 516; stricture of the urethra, 596; lesions, influence of constitutional diatheses on, 645; stenosis of trachea, 696.
Treatment; of fissure of anus complicating chronic metritis, 17; of scarlatina, 18, 257; of arsenical poisoning with dialysed iron, 19; of sycosis, 19; of pneumonia by venesection, 32; of diphtheritic conjunctivitis with quinine, 73; of pleural effusions, 85; of uterine tumors, 105; of scars of the face, 106; of pustular syphiloderma, 122; and diagnosis of ulcers, 113, 143; of ophthalmia neonatorum, 135; of syphilis, 165; of wounds, the position of iodoform in, 184; of the contagious forms of conjunctival inflammation, 189; of fungous arthritis, 208; of lung cavities, antiseptic inhalations, 218; of diphtheria, 219, 261; and pathology of Bright's disease, 225; of infantile gastro-enteritis, 238; of fracture of the skull with depression, 239; new, of irreducible hernias, 272; of heart disease, rest in, 294; of fracture of femur in children, 296; of benign tumors, 309; of fibroma, 310; lipoma, 311; enchondroma, 311; telangiectasis, 313; of styes, 331; of rupture with a new anatomical truss, 368; of obstinate vomiting, 383; of angina pectoris, 385, 414; of epilepsy, 393; of ozæna fœtida simplex, 409; of sequelæ of frozen extremities, 411; of gonorrhœa, 413, 638; of excessive sweating, 415; of tapeworm, 418; of acute chorea by massage, 432; of menorrhagia, 490; of eclampsia, 528; for gout, 529, 545; of rheumatism, 545, 732; of athrepsia, 552; of enlargement of the spleen, 556; of diabetes, 557; of inebriety, 561, 620, 701; of hydrophobia, 582; of writers' cramp, 584; of contracted finger, 585; of venereal ulcers, pyrogallic acid in, 604; local, of erysipelas, 613; of urethritis, 648; rational, of catarrh, 667; of scurvy, 668; of Bright's disease with pilocarpine, 668; of pelvic cellulitis, 718; of neglected sprains, 718.
Tribute, a graceful, 560.
Trichinæ; destruction of, 525; in adipose tissue, 555.
Trigone, incision of, 413.
Trigeminus, neuralgia cured by amputation of the vaginal portion of, 217.
Tropics, health of, 212.
Tricuspid valve, incompetence of, 137.
Troublesome labors, 406.
True disinfectants, 213.
Tubercle; of synovial sheaths of tendons, 348; infectiveness of, 374; bacilli, in sputa, easy method to discover, 636.
Tubercular; syphiloderm of nose, 6; bacteria, poison for, 550.
Tuberculosis; 385; some peculiarities explained by the parasitic nature of this disease, 176; sulphuretted hydrogen as a remedy for, 214;

bacillus, hard to detect, for diagnosis, 467; of urinary apparatus, 468; on the tongue, 528.
Tuberculous; testicle, removal of, 121; orchitis, pneumothorax and, 136; pharyngitis, iodoform in, 355.
Turbinated bodies, hypertrophy of, 31.
Tumor; dental, of jaw, 17; steatomatous, obstructing labor, 75; uterine, treatment of, 105; myo-fibromatous, removal of, 111; of the brain, 160, 187, 397; benign, treatment of, 309; sebaceous, 314; of the sphenoidal cavities implicating vision, 472; of lachrymal gland, 473; ovarian, 540; fibroid, of the uterus, 540; nature's removal of, 555; lymphomatous, of mediastinum, 572; myxomatous, of posterior cervical region, 629.
Turpentine; for tænia solium, 468; peculiar reducing substance in urine, from internal employment of, 519.
Turpeth mineral; in acute laryngitis, 557; in croup, 582.
Two-headed monstrosity, 154.
Tympanites in cases of fibroid tumors of uterus, 696.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

THE HYPODERMIC SYRINGE.

BY HUGO ENGEL, A.M., M.D.,
Of Philadelphia.

That there are still many physicians who, while in active practice, never have made use of the hypodermic syringe, is a fact which cannot be questioned. At the same time we must admit that there are good reasons for this apparent neglect in not employing one of our most efficient methods of administering medicine to the sick. There are many physicians who have never seen a subcutaneous injection performed, who have studied at a time when its application was unknown, but who may have read of the many fatal accidents which occasionally followed its employment; and such practitioners necessarily are afraid of employing means with the use of which they are not thoroughly familiar. We are convinced, however, that no physician who is thoroughly acquainted with hypodermic medication will ever fail to make use of the same, if opportunity offers itself, and we will endeavor in the following to impart the information most desirable, having all the time the wants of those practicing physicians in view who, by the force of circumstances, failed to obtain this useful knowledge. To this end we will first speak of the instrument itself, then of the manner in which the remedies to be injected should be dissolved, and of the medicines and the different solutions usually employed this way; afterward we will mention the parts of the body into which the injections should preferably be made; the precautions to be taken and the dangers to be avoided; and lastly, we shall name the diseases in which the hypodermic method is especially useful, and in which it is frequently our only available means of success.

Generally speaking those syringes which command the highest prices are the best. We prefer a metal case, a glass cylinder, and a graduated piston rod. But a physician may buy any hypodermic syringe which fulfills the following conditions. When water is drawn into the syringe or ejected from it, the operator must note that the piston does not give a sudden jerk; because, whenever such is the case, the cylinder has not all over the same width—a serious fault, making the syringe useless. Further, when the needle is attached and the fluid injected under the skin, not a drop of the solution should pass behind the piston-head; if it does, the latter must either be made tightly fitting or another syringe has to be procured. None of the fluid should pass out between the glass cylinder and the metal case. Then the physician must see that the rod is correctly graduated. Some syringes, when indicating, for instance, five minims, contain in reality seven or more; if the operator is not aware of this fact, dangerous results might ensue. It is necessary, therefore, that we should be well acquainted with the exact capacity of the syringe, and know how far this corresponds with the graduation on the rod. Lastly, the needle must be without a leak, very sharp, and at least one-inch in length. Any hypodermic syringe answering the description given, will fulfill its purpose.

Of all remedies, morphia is most frequently used by the hypodermic method. The dose of

this drug, when injected the first time under the skin of an adult, should be gr. $\frac{1}{6}$. The best plan for the physician to adopt is to carry with him a number of powders, each containing morphiæ gr. $\frac{1}{6}$, and to dissolve one of them in about ten minims of lukewarm water immediately before use. Morphia might also be kept in solution, for which we will give in the following a recipe. All other remedies are better kept in solution.

Before enumerating the different solutions generally used by the hypodermic method, we wish to say the following: The dissolving fluid should be distilled water, and hot at the time of preparation. To each ounce one grain of crystallized carbolic acid should be added, and the solution then be filtered through filtering-paper into a bottle, the wide mouth of which can be tightly closed by a glass stopper. Exposure to air must be avoided, and when using such a solution, it should be clear and without sediment. The following solutions are those generally employed in the practice of medicine. To prevent repetition we omit the addition of the carbolic acid, one drop of which should, as mentioned, be added to each ounce of solution:

MORPHIA.

℞. Morphiæ, sulphat., gr.xvj
Aquæ destill., f℥j. M.
Sig.—For hypod. use, ♏v–gr. $\frac{1}{6}$.

ATROPIA.

℞. Atropiæ sulphat., gr.ss
Aquæ destill., f℥v. M.
Sig.—Atrop. ♏vj–gr. $\frac{1}{100}$.

STRYCHNIA.

℞. Strychniæ sulphat., gr.j
Aquæ destill., f℥ss. M.
Sig.—Strychnia ♏v–gr. $\frac{1}{48}$.

QUINIA.*

℞. Quiniæ sulphat., gr.xxj
Solut. acid. tartar. concentr. f℥j M.
Sig.—♏xx–gr.vij.

PILOCARPIA.*

℞. Pilocarp. muriat., gr.iv
Acid. muriat., ♏j
Aquæ destill., f℥ss. M.
Sig.—♏x–gr. $\frac{1}{6}$.

Besides the foregoing the following medicinal substances are frequently administered by the hypodermic method. Ergot,† a special fluid extract, is manufactured for this purpose, the dose being about ♏vj; arsenious acid; Fowler's solution, in the dose of ♏iv and more, is the most convenient form for this acid; iodine, Lugoll's solution, in the dose of ♏v and more, is admirably adapted for the hypodermic administration of iodine; solutions of nitrate of silver, corrosive sublimate, and of caustic potash; further, chloroform, chloric ether, brandy, and aqua ammoniæ, are also frequently injected subcutaneously, for purposes later to be mentioned. There are still other drugs, as hyoscyamia, woorara, etc., employed in the same manner, but those enumerated above are so commonly made use of, that they should be kept on hand by every practicing physician.

Whenever a hypodermic injection shall be made the following conditions have to be observed: Being convinced that the instrument is in perfect order (see above), we either draw the exact amount of the solution to be used into the syringe, or, the better plan, we fill the syringe totally with the solution, and by moving the small screw down the piston rod to the number of minims wanted, prevent the possibility of a larger amount than intended escaping. We prefer the latter plan, as we can this way better get rid of all the air in the syringe, a very important matter. This is best done by holding the syringe with the needle upward, and then allowing all air to escape by pushing the piston up, until all the air is out and only the fluid escapes. By all means we must be certain that the syringe contains no air. We then select the locality for injection, and here we prefer the place as near as possible over the part to be acted upon. If there is no special part, but we wish to make a general impression, then the injection should be made in the upper arm, near the deltoid, or into the abdominal walls, or into the integument covering the inner and anterior side of the thigh. At these places the least pain is felt and absorption is more rapid. Next, we must be exceedingly careful not to push the needle into a vein, as in such a case the most alarming symptoms, and even death, may ensue. Having selected the place, a part of the skin is lifted up with two fingers and the needle thrust rapidly into the subcutaneous areolar tissue, and the solution injected. The needle is then withdrawn and a finger placed immediately over the opening in the skin, and held there, while the operator tries, by moderate pressure, to spread the injected fluid through the cellular tissue. If, either in consequence of a rusty needle or of air having been present in the fluid, or from some other cause, signs should later develop themselves denoting the formation of an abscess, we will mostly be able to prevent this, or limit it decidedly, by painting the part

* No carbolic acid.

† This preparation is apt to clog up the hypodermic needle, and the latter, as well as the syringe, must always be thoroughly cleansed with hot water when this fluid extract has been used.

three times daily with tincture of iodine, till all swelling and hardness have disappeared. Should, notwithstanding this precaution, an abscess form, only a very small opening should be made with a sharp-pointed bistoury. Experience has convinced us that this procedure is far better for the patient, and that the abscess heals with greater rapidity than when it is laid open with a long cut. But if the injection is carefully made, and the precautions mentioned are observed, the moderate and soft swelling following a hypodermic injection will generally disappear within forty eight hours.

We come now to an important question: In what diseases should hypodermic injections be administered? As mentioned before, we will not be able to give every indication, but we will take up the different solutions described, and try to illustrate by instances the indications for their employment.

Perhaps at 2 A.M. the bell rings and the physician is called to a patient, whom he finds in agonizing pain. It may be a case of gastralgia, of colic of any kind, or of any other severe pain. The first indication would always be to relieve the suffering of the patient, and the doctor should not leave the case until that end is gained. Nothing will act as rapidly as a hypodermic injection of morphia, repeated if necessary, should the first not have brought decided relief. In the majority of cases the physician will be able to return home within less than half an hour, the patient enjoying a quiet sleep. The further management of the case may be left for the visit the next morning.

In cases of delirium tremens our chief anchor is still opium, especially in cases where the weakened condition of the heart forbids the employment of chloral. The internal administration of opium is mostly for a long time unsuccessful, as the power of absorption by the vessels of the alimentary canal is, in such cases, on account of the affection of the mucous membranes, mostly below the normal. Here the subcutaneous injection of morphia will act like a charm, and will surprise, by its rapid effect, the physician who used to rely always on the internal administration of opium in these cases. A further indication for the employment of morphia by this method is found in all those cases in which we wish to administer this drug but cannot give it internally, on account of the existing nausea and vomiting. Peritonitis is one of these diseases. In fact, whenever we wish a rapid action of morphia, or when, the use of this drug being indicated, certain conditions of the patient prevent us from administering it successfully by the mouth, the hypodermic method should be employed.

The published record of several cases seems to show that in the hypodermic administration of morphia we possess as reliable an antidote in cases of poisoning by belladonna, as atropia, subcutaneously injected, has proven successful in poisoning by opium. Stubborn cases of myalgia, especially of lumbago, will often yield to combined hypodermic injections of morphiæ gr. $\frac{1}{6}$. and atropiæ gr. $\frac{1}{100}$. In cases of failure of the heart's action, especially when the capillaries of the surface of the body seem to be emptied of blood, the administration of atropia by the same method has given the happiest results.

Strychnia is perhaps our most reliable medicine for paralysis, after any inflammatory condition which might have caused the latter has passed away. The most effective way of employing this drug in such cases is by the hypodermic method; the remedy being injected subcutaneously over the parts affected. Especially in local palsies this method is by far the most effective.

While in common cases of malaria we will succeed in effecting a cure by the internal administration of quinine, or by administering it by the bowel, in many cases of the congestive type we will have to employ this remedy hypodermically, either because the time is too short, so that we could not prevent the next, perhaps fatal, paroxysm by the internal use of quinine, or because the irritable condition of the stomach excludes the latter method. Besides, we gain this way the same effect with a much smaller quantity of the drug —one-third of the internal dose only being required—an item which, under certain circumstances, is of no small importance.

There are few modern remedies which have met with such a success as jaborandi or its alkaloid, pilocarpia. Whenever we wish to produce a powerful diaphoresis, stimulate absorption and increase the flow of urine, and when, for reasons which must be apparent to every physician—as unconsciousness, coma, inability to swallow, or irritability of the stomach, conditions frequently met with in morbus Brightii—we cannot employ this remedy by the mouth, the hypodermic injection of pilocarpia is indicated, and has saved many a patient from a premature death.

Ergot has been employed successfully by the hypodermic method, in cases of enlargement of the spleen and of the thyroid gland. It is then injected over the hypertrophied organ. If we aim to produce contractions of the uterus within as short a time as possible, or to stop internal

capillary hemorrhages, the remedy should be used subcutaneously.

Arsenious acid, or the arsenite of potassium, in the form of Fowler's solution, has been successfully employed in the manner mentioned, in cases of chorea and other nervous diseases, especially when the irritability of the stomach prevents the internal administration of this powerful drug. Some cases of leukæmia, lymphadenoma, have been reported as cured by this method.

Lugoll's solution, injected subcutaneously, is known to stimulate absorption, and is employed mainly in cases of hypertrophy of the thyroid gland, of enlargement of the spleen, and to induce absorption in cystic formations.

The following remedies have been employed hypodermically for the purposes indicated: Solutions of nitrate of silver in cases of nævi or deep-seated neuralgic affections, as sciatica; suppuration follows, and the nævus disappears, and the neuralgia is often benefited by this procedure; solutions of corrosive sublimate, to effect a rapid cure in constitutional syphilis; here the injections are preferably made over the glutei muscles; chloroform has been injected subcutaneously in neuralgia; chloric ether, brandy, and aqua ammoniæ in cases of collapse, and a solution of caustic potash to destroy hair-growth, one drop of the solution being injected near each bulb. This is considered the most reliable and never failing procedure to effectually prevent any further growth of hair in that locality. As mentioned above, many other remedies have been used by the hypodermic method, but for these we must refer the reader to works on this subject.

The main points in favor of all hypodermic medication are the following: The rapid action of the remedy, which enters the circulation immediately, without having to undergo chemical alteration in the stomach; the fact that drugs can be introduced into the system when the irritability of the stomach would forbid their administration by the mouth; and lastly, the possibility of getting the full effect of a medicine in cases of inability to swallow or of unconsciousness.

But, in conclusion, we wish to draw the attention of our readers to one great danger in the employment of hypodermic injections of morphia. Most cases of morphia habit find their origin in the reckless employment of such injections by the attending physician. The latter should never discharge his patient, in cases where a frequent use of this remedy by the subcutaneous method was necessary, until he has convinced himself, by gradual withdrawal of the drug, that no habit has been established, and till the patient has not experienced any restlessness for several days, and enjoyed a quiet sleep for several nights, without the use of morphia. A physician who, in such cases, neglects this precaution, is morally, if not criminally, responsible, if the deplorable habit should become established. We may add, that the administration of bromide of sodium, in doses of thirty grains, three or four times daily, will greatly assist in making the gradual withdrawal of morphia in these cases less painful and easier for the patient, and that the fluid extract of Jamaica dogwood, in doses of twenty to forty drops and more, will assist in obtunding sensibility and procuring sleep. Whenever we are forced to continue, in any case, hypodermic injections of morphia for a longer time, we always engage, after the total withdrawal of the remedy, a reliable nurse for two days and two nights, to watch the patient, as the statements of the latter under such circumstances have to be taken *cum grano salis*. Besides, the contraction of the pupil, even in dim light, will generally tell the physician that his patient is still continuing the morphia.

507 *Franklin street.*

LACERATION OF THE FEMALE PERINEUM.

BY H. V. SWERINGEN, M.D.,

Of Fort Wayne, Indiana.

Read before the Indiana State Medical Society, May 11th, 1882.

My object in presenting for your consideration a few cases of lacerated perinei, is to hear, as an interested spectator, the subject discussed with especial reference to the much disputed point, the proper time for operative procedure. This being my purpose, it will not be necessary to enter into its etiology and prophylaxis.

I commenced the preparation of this report a week ago to-day, subject to the interruptions common to the physician. A mere glance at the literature of the subject was taken, and, therefore, Goodell and Thomas were but hastily consulted. But I am here to relate my own experience, and not that of the excellent authorities quoted, however difficult it may be to divest myself of that gregarious spirit which is disposed to follow the track pointed out by a few leaders.

Case 1.—In the spring of 1876 Mrs. H., a healthy, robust lady, residing on Virdlinger Avenue, Fort Wayne, Indiana, æt. 35 years, primipara, was delivered, by forceps, of a healthy child, which delivery resulted in a complete rupture of the perineum, which was immediately

sutured by three silver wires, after which union speedily took place by the first intention.

Case 2.—On the last day of October, 1880, Mrs. D., residing at No. 71 West Wayne street, Fort Wayne, Indiana, a rather delicate lady, æt. about 30 years, primipara, was delivered, by forceps, of a bright, healthy child, which delivery resulted in a partial laceration of the perineum; two black silk sutures were at once introduced and carbolized injections employed twice daily; union was not effected; septicæmia developed, and death occurred on the twelfth day of November.

Case 3.—On the 5th day of October, 1880, Mrs. E., a healthy, well developed lady, aged about 25 years, residing at No. 11 North Cass street, Fort Wayne, Indiana, primipara, was delivered, by forceps, of a healthy babe, resulting in the laceration of the perineum, to a point about midway between the fourchette and the sphincter; no sutures were employed, simply carbolized vaginal injections were resorted to, night and morning, and the patient directed to assume a lateral posture, without, however, fastening the knees together; union took place rapidly, without suppuration.

Case 4.—On the 17th day of February, of the present year, 1882, Mrs. D., a healthy, vigorous lady, aged about 26 years, primipara, residing at No. 14 Wilt street, Fort Wayne, Indiana, was delivered, instrumentally, of a healthy child, with the result of a complete laceration of the perineum; the rupture was so extensive that for several days it was impossible for her to retain her fæces. No sutures were introduced, carbolized vaginal injections were employed night and morning, and the lateral decubitus rigidly enforced, without tying the knees together; union by the first intention was speedy and perfect.

Thomas, in his great work on the Diseases of Women, on page 129, makes use of the following language:—

"Even when the rupture has been complete, it has been asserted that spontaneous cure has taken place, but such reports need confirmation. Pen once affirmed that he had seen a woman thus injured, and who passed her fæces involuntarily, entirely recover. De la Motte declares that thirty years afterward he met and examined Pen's patient, in Normandy, and found that no recovery had occurred."

In view of the foregoing extract, I feel obliged to give in full the address of this case, which is as follows: Mrs. James M. Dickson, No. 14 Wilt street, Fort Wayne, Indiana; the address of the nurse who attended her is Mrs. John H. Waterman, 157 Van Buren street, Fort Wayne Indiana.

Case 5.—On the 27th day of last month, April, 1882, Mrs. M., a lady in ill health, residing on Walnut street, Fort Wayne, Indiana, was delivered, by forceps, of her second child. As a result of this delivery, the perineum was ruptured down to the sphincter; its examination revealed, also, an old, ununited, partial laceration, which occurred during her first accouchement, nearly two years prior, while residing in another town, and while under the care of another physician. She was now directed to lie constantly, on either side, with her knees tied together, and carbolized washes were ordered to be employed night and morning; no sutures were introduced. Up to the date of the present writing, May 6th, 1882—on which date her babe died in a spasm—nature has entirely failed to effect a union of the severed parts. She is now taking iron, quinine, cod-liver oil, etc. No history was obtained from her, save a general complaint, extending over a period of several years, of an indescribable illness. Her appearance is anæmic, leucocythæmic, or that of general debility, with all that that rather indefinite term implies, and she presents a diathesis not wholly unlike that denominated strumous. I believe that in this case, when her general health is sufficiently improved, union of the ruptured parts will take place by merely revivifying their surfaces and enforcing the lateral decubitus, without resorting to sutures; the latter would have been, in my opinion, unsuccessful in this case.

I have now recorded my own personal practical experience in lacerations of the female perineum. As will be observed, it is by no means extensive; but, diminutive as it is, it has not failed to be suggestive of the following propositions:—

1. If natural, unaided parturition, which we must regard as a healthy physiological function, is not unfrequently followed by pathological and necrological results, the immediate closure of a ruptured perineum by sutures tends to favor these results, by reason of the sources of infection their puncta create. The fact that in many instances these results do not follow the operative procedure does not in the least detract from the soundness of the position here taken.

2. An open, unsutured, non-uniting, but cleanly rupture is certainly not so likely to become infectious as a closed, sutured, ununiting and therefore uncleanly laceration, leaving out of the consideration the foci of infection produced by the sutures alone. Upon this point,

Dr. Goodell writes as follows: "The fears of septicæmia entertained by some physicians are purely hypothetical; for, although the suture-tracks form, in one sense, new foci of infection, yet they close up a raw surface whose area is vastly larger than theirs.

But there is a certain proportion of cases in which these raw surfaces, though sutured, do not unite, and in which, therefore, the suture-tracks increase largely the area of exposed absorbing surface, and hence increase, also, the risk of danger. It is in the interest of this certain proportion of cases that I write; for if it can be shown that death occasionally results from septicæmia, due to the immediate operation, and very seldom if ever from the remote, and that nature alone, if let alone, with favorable conditions, would be more frequently successful in effecting a cure, our rule of action is made plain. Parturition, under the most favorable circumstances is attended with great risk, and if we can well postpone an operation which would have the least tendency to increase this risk, it is our duty to do so.

3. If, then, it could be established beyond a reasonable doubt, that, all things being equal, in all cases of ruptured perinei in which art succeeds in effecting an immediate union nature would likewise prove successful, the immediate operation should never be attempted.

I feel deeply the importance of this subject, because I shall never be able to banish from my mind the impression that the case I lost died of septicæmia, directly traceable to the immediate operation.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF LOUIS A. DUHRING, M.D.,

Professor of Dermatology.

Reported by Fred. A. Taylor.

Case 1.—Eczema Rubrum, Infantile.

Our first patient is an infant about six months old, who has marked eczema rubrum of the face, showing also erythematous lesions of the same disease on the forearms and hands. It is much more marked on the face, which is the usual seat of the disease in infants. Here it is characterized by crusted patches, resulting from broken down vesicles and pustules. These patches which you see did not come out as such. The primary lesions were vesicles, papulo-vesicles or pustules; these became scratched, and broken down and dried; then new lesions appeared, which were again scratched down, and drying with the others, have ultimately resulted in these patches. This is the usual course in such cases, and hence, as the patient is not generally brought to us for a month or two after the disease has made its appearance, the original lesions are rarely seen. This case, however, exhibits on the backs of the forearms and hands an eruption of the papulo-vesicles, evidently of recent appearance, which are the typical, original lesions in this form of eczema. The case is typical of what you will frequently meet in practice, as this form of eczema is common in young infants.

The treatment is in some cases easy and in others not. It is hard to predict in any given case what its course will be. In the case before us the general health is good, and no internal treatment is indicated. A not very stimulating local treatment is needed. We will employ an ointment of boracic acid, a drachm to the ounce of vaseline, to be rubbed in three times a day; the parts to be previously washed with a lotion containing three drachms of boracic acid to the pint of water. We will continue this for a week, and if no benefit results, we will substitute an ointment composed of equal parts of tar ointment and vaseline.

Case 2.—Tubercular Syphiloderm of Nose.

The next case is that of a woman, about forty years of age, who has been under treatment two weeks for a tubercular syphiloderm. The lesions occupy both sides of the nose, extending somewhat upon the cheek. They are broken down and are in a state of involution; they are, however, still much swollen, indurated, of a reddish, violaceous hue, clearly outlined against the surrounding healthy tissue. You notice also, on the nose, two or three characteristic bluish cicatrices. The history of the case does not concern us, aside from the appearance of the secondary symptoms. She has had the skin disease, she says, six or eight months. It has improved markedly under the treatment we have given her. Internally she has had the following:—

℞. Potassii iodidi, ʒij
Hydrargyri biniodidi, gr. iss
Tinct. cinch. comp., fʒiv. M.

Sig.—One teaspoonful, with water, after each meal.

Locally, we used, for the right side of the nose, an ointment composed of equal parts of vaseline and oleate of mercury, of thirty per cent. strength. On the left side we used ammoniated mercury, thirty grains to the ounce of vaseline. As you can see, the ammoniated mercury has proved the most valuable by far in this case. The treatment will be continued.

Case 3.—Vesicular Eczema of the Leg.

This man, about fifty years of age, shows a diseased condition of the lower part of the leg. Two or three months ago he received some injury in this region, which was followed in a few weeks by an eruption of vesicular eczema. The lesions have broken down and crusted, and tend to form patches, as in the case of the child whom you just saw. On further examination we find that the disease has appeared on the other leg and both arms. The symmetry is striking.

The patient is rheumatic, and is somewhat

constipated. His treatment, consequently, will be the administration of a saline aperient every morning before breakfast, so that his bowels will be moved once a day; liquor potassæ, in ten or fifteen minim doses, three times a day, after meals; and locally, the black wash, to be dabbed on three times a day, for ten minutes at a time, and the sediment allowed to dry; this to be followed by an application of oxide of zinc ointment. Under this treatment the disease should begin to disappear in a week or ten days.

Case 4.—Furunculosis of the Buttocks

A boy, about ten or twelve years old, and of delicate health, presents extensive disease of the buttocks, characterized by a number of boils, about a dozen in all, variously disposed over the surface; some running together and forming inflamed areas, in various states of evolution; some just making their appearance, others fully developed, and others passing away. The disease is known as furunculosis; in common language, boils.

Many different methods of treatment are advocated for boils, but there is no general rule that can be applied. The treatment must be adapted to each special case, taking into consideration the general health of the patient, the mode of appearance and the location of the disease, whether they have ever appeared before or not, etc. In this case the boy is anæmic, and gives us a distinct history of malaria; and we will prescribe five drops of the tincture of the chloride of iron, to be taken three times a day, after meals, and five grains of quina, to be taken in one dose, every night. This, I believe, will speedily effect a cure.

Case 5.—Chronic Eczema Rubrum of the Leg.

The next case is one of chronic eczema rubrum of the leg complicated with ulcers, occurring in a man about sixty years of age. The disease forms a continuous patch surrounding the leg; the lower half of a violaceous hue and crusted, the upper part of a more acute appearance and showing vesiculation. Just above the ankle is an ulcer, the size of a half dollar, and scattered over the leg are three or four smaller ones. These ulcers will tend to enlarge and run together, forming ultimately one of the chronic leg ulcers so often met with.

One of the best modes of treating these ulcers is that which we have employed in this case, namely, the use of the rubber bandage. Under this treatment he has slowly improved. Sometimes the use of the rubber bandage tends to aggravate the eczema, but in many of such cases the bandage may be borne by first covering the leg with a cloth. We will continue the bandage on the lower part of the leg, and on the upper part where the disease is more acute and accompanied with itching, we will apply a powder composed of equal parts of oxide of zinc and starch.

Case 6.—Hyperidrosis of Feet and Hands.

A man about thirty-five years of age, who is troubled with excessive sweating of the feet, comes to us for advice. The soles of his feet, you see, present a whitish, macerated and somewhat excoriated appearance, most marked about the heels, where minute beads of sweat may also be detected. The condition you see here is characteristic of the disorder, which is known technically as hyperidrosis. He has been troubled with it, he says, for six months. The palms of the hands are also affected, but he has attributed that to the nature of his employment, which, however, has nothing to do with it.

The treatment to be employed is entirely a local one. We will use a preparation of salicylic acid, composed as follows:—

R.	Salicylic acid,	4 parts
	Starch,	6 parts
	Silicate of magnesia (or talc),	90 parts.

This silicate of magnesia is what is known in the shops as Venetian talc. The powder has been used extensively abroad, particularly in the Prussian army. If the case does not improve in a week or two of this treatment we will substitute the tincture of belladonna, to be applied twice a day. In many cases this produces a remarkable effect.

Case 7.—Mucous Patch.

The next patient, a young man, about twenty-five years of age, has been under treatment about six months for a papulo-squamous syphiloderm, and mucous patches; the primary lesion having occurred about a year ago. We have not seen him for some time. As is usual in these cases, after the symptoms have disappeared under treatment, the patients regard themselves cured, and cease their visits. In this case the eruption has entirely disappeared, but he returns to us with a mucous patch, the size of a dime, irregular in outline, occupying the inner surface of the right side of the lower lip. It made its appearance three months ago, he says, and is continually increasing in size.

The treatment to be employed for mucous patches is the local application, by means of a camel's hair brush, of the acid nitrate of mercury, in the strength of one part to eight or ten of water; or a solution of nitrate of silver, ten or twenty grains to the ounce. Internally, we will give him the protiodide of mercury, in doses of one-sixth or one-fourth of a grain. The mercurial treatment should be continued for one or two years, and we always earnestly advise this, though we know our advice may not be heeded.

Case 8.—Eczema, with Dermatitis.

This woman, about forty-five years of age, shows a diseased condition of the back of the right forearm and hand, characterized by a continuous, markedly inflamed, somewhat crusted patch. Six weeks ago she was troubled by severe itching in this region, probably due to a beginning eczema. She applied for relief to some druggist, who, though probably entirely ignorant of the nature of her trouble, did not hesitate to prescribe some stimulating preparation, the application of which was immediately followed by this severe dermatitis, which has continued to the present time. The case is but an illustration of what frequently happens from the reprehensible practice of druggists assuming the function of the physician.

We will use a preparation of lead water and

oxide of zinc ointment, to allay the inflammation, and will ask to see the case again in a few days.

Case 9.—Excoriations from Pruritus.

An interesting case is presented here, in a woman, about fifty years of age, who shows strikingly marked excoriations over the entire surface of the back, shoulders, and upper part of arms, together with erythematous streaks and patches, all the result of violent scratching. As there are no lesions that would indicate anything else, her itching is due either to pediculosis, *i. e.*, body lice, or to pruritus. A careful examination of the underclothing is always necessary in such cases, to determine the question, the patient's statements not always being sufficiently reliable. The picture presented is a striking illustration of the excoriations patients will sometimes produce on themselves in cases of skin disease.

Over the shoulder blades in particular you see how the skin has been denuded in patches and streaks, an inch or even two inches in length. The examination for pediculosis will be made, and the case treated according to the result.

To allay the itching we may employ the preparation of carbolic acid frequently prescribed in this clinic, viz:—

℞.	Acidi carbolici,		ʒ iss
	Glycerinæ,		f ʒ iv
	Alcoholis,		f ʒ j
	Aquæ,	ad	Oj. M.

Sig.—Apply freely thrice daily, as a lotion. (No pediculi were found.—Rep.).

Editorial Department.

Periscope.

Concealed Uterine Hemorrhage.

Before the Obstetrical Society of London (*British Medical Journal*) Dr. Horne read the notes of a case of concealed hemorrhage occurring in a woman, Mrs. B., aged 34, pregnant with her seventh child, otherwise healthy. Previous labors had been easy and uncomplicated. On November 11th, 1881, she went to the Rotunda Hospital; she was then weak and pale, with a moist skin, and was complaining of a feeling of extreme faintness, and of pain shooting down to the groins. She stated that on the previous day she had been exercising rather unduly. Examination showed the external os uteri to be patulous, the internal being closed. No presentation could be made out. Dr. Horne tried to rupture the membranes, but got no liquor amnii, nor could the fœtus be felt. There was the abdominal tumor, and the woman's history that she was far on in pregnancy; but palpation and the stethoscopic examination gave only negative results. The vagina was, therefore, plugged, and on the second day the fœtus, still-born, was found in the vagina, covered with the unbroken membranes, and the placenta attached. A large clot of blood was subsequently expelled from the uterus, and the woman made a good recovery. Dr. Horne had found records of thirty-seven cases; in twenty-three the mother died; in all, the child was still-born. Out of one hundred and ten cases, compiled by German authors, fifty-six mothers died; while seven children were saved. The cases were to be recognized by the presence of all the symptoms of hemorrhage, without visible bleeding, a tense uterus with pain over it, but at no time true labor pains. The first question that suggested itself was, was the woman pregnant or not, for no fœtus could be felt? The question of treatment was an important one, and one on which some difference of opinion existed. Was it better to treat it like a case of ordinary accidental hemorrhage, or procrastinate, in order to conserve the patient's strength? The latter was the line adopted in the present case, and with the favorable result recorded. Dr. Kidd thought that the great difficulty was the diagnosis. He saw a case of a lady who, when eight or nine months' pregnant, fell down stairs; pain set in, soon followed by collapse, which passed off in a few hours. He found the uterus enlarged and doughy; the os was closed; there was no hemorrhage in the vagina. He introduced a Barnes' bag, dilated the os, and delivered as quickly as possible; but the woman died. The best practice in such cases was to dilate the os and deliver as quickly as possible, unless the woman were actually collapsed and pulseless. Dr. Denham related a case which had occurred in Dr. Johnston's practice. A lady, between eight and nine months' pregnant, was suddenly seized with a fainting fit, and all the symptoms of hemorrhage except external bleeding, not a single drop appearing externally; she died, and the post-mortem examination showed the placenta to be adherent all round its margin, but detached on its flat surface completely, and a large hemorrhage separating it from the uterine wall. He agreed with Dr. Kidd, that dilatation of the os and rapid delivery was the best treatment in such cases, but preferred to use his fingers instead of Barnes' bag. Dr. Atthill said that in the 14,000 cases which had been delivered during his mastership of the Rotunda Hospital, this was the only case of concealed hemorrhage, showing how rare it was. In all the recorded cases in which the membranes were ruptured, the patients died; he did not, therefore, think the practice a good one; and, considering the sudden emptying which occurred under such circumstances, there was every reason to believe that it would tend to produce fresh hemorrhage. He therefore advised that, unless the woman were dying or sinking, the membranes should not be ruptured, or delivery rapidly effected, unless uterine action could be first induced. Dr. Macan said that the rule on the Continent was not to rupture the mem-

branes unless the uterus was acting, for, by doing so, the only thing which restrained the hemorrhage—namely, the intra-uterine tension—was relieved. Pain he regarded as an important diagnostic. Women died from shock which was quite out of proportion to the amount of blood lost. He did not advise rupturing the membranes, but dilated the os by means of Hegar's dilators, as they were more easy of application than Barnes' bag. The utter want of uterine action in such cases made him think there must be something radically wrong with the uterus itself. Dr. Dill had long been impressed with the belief that the collapse was due to the shock of the hemorrhage, and not to the amount. He thought that a diagnosis could generally be made by the (1) history, (2) local pain, and (3) collapse. He advised an expectant line of treatment, sustaining the patient's strength, giving ergot, and encouraging uterine action.

Suicide.

The *Lancet* says: The distressing increase in the number of suicides has been commented upon again and again, but the facts which have been observed by different writers have recently been got together and published in such a complete form by the *Economiste Français* that it may be well to give a concise summary of them. Beginning with France, the writer points out that from 1827, since which year there has been a register of the number of suicides known to have been committed, the annual average has risen from about 1500 to upward of 6000, the number in 1851 having been 3639, or one suicide for every 9833 inhabitants, while in 1879 there were 6496 suicides, or one for every 5681 inhabitants. This increase of 78 per cent. is not peculiar to France, for in Prussia, from 1873 to 1877, the increase was 53 per cent., and in Bavaria 60 per cent. The proportion per million inhabitants rose from 66 in 1860-70 to 81 in 1875 in Belgium; from 74 in 1865 to 144 in 1877 in Austria; from 30 in 1874 to 41 in 1877 in Italy; from 23 in 1872 to 35 in 1876 in Russia; from 233 in 1874 to 257 in 1876 in Denmark; and in England, from 67.2 in 1866 to 69.2 in 1877.

It is a well-known fact that the great majority of suicides are committed by men, the average proportion of the different countries of Europe being 80 per cent. of men to 20 per cent. of women. Signor Morselli, in his well-known work entitled, "Il Suicidio," recently reviewed in our columns, holds that more women, proportionately, commit suicide in the country than in towns, and the figures which he is able to quote confirm this argument. In England the heaviest contingent of suicides is among men of from forty-five to fifty-five years of age. Among women suicide is most frequent in Sweden, Denmark, Bavaria, Prussia, Saxony, and Austria, between the ages of twenty and thirty, and in England between the ages of thirty five and forty-five.

It has been established by M. Bertillon that widowers and bachelors commit suicide more frequently than married men, the general proportion being about 54, as compared with 46 per cent.

There is a very great difference in the mode of committing suicide, as may be seen from the following table, showing the proportion per 1000 in five of the principal countries of Europe:—

	England.	*Prussia.*	*Italy.*	*Belgium.*	*Switzerland*
Hanging	368	608	167	545	430
Drowning	208	182	308	228	267
Firearms	46	109	244	118	70
Stabbing	206	54	55	39	67
Poisoning	94	30	61	23	33
Falling from height	94	9	113	15	11
Suffocating	94	3	22	4	13

In France 45 per cent. of the suicides are by hanging, 29 per cent. by drowning, 11 per cent. by shooting, 7 per cent. by suffocation, and 3 per cent. by jumping from high places; whereas forty years ago the most frequent mode of suicide in France was by drowning. As might be expected, suicide by drowning is more frequent in summer than it is in winter, the prevalent modes in the winter months being hanging and poison.

The most important chapter in this essay is that which relates to the causes of suicide, and the *Economiste Français* states that out of 30,128 cases of suicide registered in France during the years 1875 to 1879, 9175 were due to cerebral derangement, 5814 to physical suffering and various misfortunes, 4937 to love, jealousy, and dissipated conduct, 4035 to family bickerings, and 2867 to poverty. In the statistics of Prussia, from 1869 to 1877, the first place is held by mental disease, domestic afflictions and misconduct, physical suffering, and jealousy coming last. Mental derangement comes first in the causes of suicide in Belgium, Italy, and several other countries quoted by Signor Morselli, who asserts that altogether the suicides due to this cause are a third of the whole. It is almost a truism to say that the number of suicides has always increased or decreased according to the state of the country. Thus, in Vienna, the number of suicides, which had been 91, 141, and 153 in the three years preceding the financial crash of 1873, rose at once to 216, while after the dearth of 1854 the number of suicides rose from 3415, 1942, 991, and 150 in France, Prussia, Austria, and Belgium, to 3810, 2351, 1066, and 189.

While the number of suicides is greater in towns than in countries, it is also much greater among educated than among illiterate people. This is a rule to which there is no exception, Germany having a much larger proportion of suicides than Spain or Russia, and Belgium than Ireland. In most countries suicide is much more prevalent among Protestants than it is among Catholics, and especially among Jews. Herr Wagner, whose researches in regard to the causes of suicide are very well known, states that in Prussia, out of a million inhabitants there are 159.9 suicides of Protestants, as against 49.6 of Catholics and 46.4 of Jews; in Bavaria, 135.4 suicides of Protestants, as against 49.0 of Catholics, and 45.9 of Jews; and in Austria, 79.5 suicides of Protestants, as against 51.3 of Catholics and 20.7 of Jews. Speaking generally, it may be said that in countries which are purely Catholic, suicide is at the rate of 58 to the million, in countries where the religion is partly Catholic and partly Protestant, 96 to the million, and in solely Protestant countries, 190 to the

million. Such are the figures given by the *Economiste Français* in the course of a very interesting article; but it is somewhat startling to read, by way of conclusion, that the best remedy for suicide is to be found in a good sound education, the writer having, as mentioned above; just quoted figures to show that it is most frequent in those very countries where education is the most advanced.

Hyoscyamine.

Dr. Kenneth W. Millican thus writes, in the *Lancet*:—

Hyoscyamine is a drug which apparently possesses very valuable therapeutic properties, and like many other of the alkaloids requires only to be known to be appreciated. The first case in which I employed it was one of hepatic colic. Feeling convinced, from its combined anodyne and anti-spasmodic properties, that good results might be anticipated from its administration, I prescribed it in doses of $\frac{1}{120}$ gr. every half hour until relief was obtained. The patient, a woman who had several times previously passed gall-stones, was greatly relieved after three doses, and the administration was kept up at intervals of an hour until after the spasm ceased. I have several times used it in abdominal colic, in the same doses, frequently repeated, and on all occasions with the best results; and it has also proved the most effectual remedy in relieving the painful distress of spasmodic asthma. Indeed, in this latter complaint, my patient, a long-standing martyr to the affection, admits that it has given him more ease than any other drug he has taken, and has completely displaced chlorodyne in his estimation. But, perhaps, the most valuable case of its successful administration is the most recent of all. The patient was a young woman from service who, when I first saw her, was in the most intense abdominal pain. There was considerable diffused peritonitis, and for some time the cause was uncertain. I was at first disposed to suspect, from the history, a pyæmic origin, but ultimately concluded that the peritonitis resulted from collections of fæces at the hepatic and splenic flexures of the colon. Morphia was administered, both subcutaneously and by the mouth, and attempts were made to clear the bowels by bland enemata, but all to no avail. Having pushed the morphia as far as I dared, I was obliged to withhold its further administration, for though the pupil gave indications of its action, the pain did not seem to be in the least abated by it. After some time I determined to employ hyoscyamine, which I did, in doses of one-fortieth of a grain, every two hours. At first it seemed slightly to increase the pain, but shortly after its physiological action upon the fauces and pupil became manifest the pain began gradually to subside, and a fairly fluid evacuation of the bowels ensued. From that time the patient began to mend, and is now progressing fairly well. When I first used hyoscyamine I employed the granules manufactured by M. Chanteaud, the eminent French pharmacien. But recently I have used a solution of the alkaloid (Merck's crystallized), in rectified spirits of wine, of the strength of one grain in two drachms. One minim of this solution thus contains $\frac{1}{120}$ grain of the drug, which can either be administered in a mixture with a little dill water, or may be used to form lozenges with sugar of milk.

Persistent Hymen.

So much has been made of the presence of the hymen as a proof of virginity, that the following case, coming from so high an authority as Dr. Thomas, who presented it to the New York Obstetrical Society (New York *Medical Journal and Obstetrical Review*, May, 1882) will possess much interest in a medico-legal aspect:—

A German lady, belonging to the upper walks of life, had been married eight years, but had never become pregnant. Being dissatisfied, she consulted him with regard to the cause of her sterility. In reply to his questions she said her menses were perfectly normal, she had very little leucorrhœa, and the only symptom of which she complained was a good deal of backache. A vaginal examination was proposed, and on attempting to introduce his finger Dr. Thomas found it impossible to do so, on account of the presence of an unruptured hymen. The hymen was perforated by an opening only barely large enough to admit a common sized lead pencil. The woman, however, again affirmed that she had been married eight years, and said that her husband had had intercourse with her regularly, at least once or twice a week, and that there had been nothing abnormal about it whatever. When he explained to her the condition of things she laughed and said it was impossible; she could not still be a virgin. Her husband, whom she was requested to send to the speaker's office the next morning, came, and he also laughed when informed that his wife was a virgin, and told Dr. Thomas, in a pleasant sort of way, that he was a *farceur*. He was about thirty-eight years old, of good figure, and said that his sexual vigor was perfect; before his marriage he had been something of a man of the world, and knew very well what it was to have intercourse with women; he had been married eight years, had had intercourse with his wife regularly, and in a perfectly normal way. Having now placed himself in such relations to the man that he would have to prove his position, Dr. Thomas requested him to bring his wife to his office the next day, which he did. Placing the woman in position, Dr. Thomas separated the labia, and showed to her husband the exact state of things. He was amazed, and could only reiterate that intercourse had been regular during the eight years of their married life. It was proposed to remove the hymen and put in a glass plug; but the husband desired him to wait a week, for he thought that in the meantime he could make all right. At the end of the week, however, the man returned, and said he now recognized that he had never had intercourse with his wife in the proper way, but how he had been deceived during these eight years he could not possibly understand. The woman was afterwards etherized, the hymen was removed, and a glass plug was introduced. Her husband said that now everything was changed, greatly for the better.

Retractile Albumen.

The *Lancet* says, editorially: A distinction was drawn first by Bouchard, in 1880, between retractile and non-retractile albumen, and he sought to establish the clinical significance of the two varieties. When albuminous urine is coagulated by heat, the precipitate sometimes has a homogeneous appearance, but sometimes is in the form of definite flocculi. The latter he regarded as the normal albumen of the blood, which could only pass out by the kidneys if there was an actual alteration of the renal filter. On the other hand, the non-retractile albumen is altogether abnormal, dialysable, and capable of passing out through the kidneys, although these are in a normal state. Thus the character of retractility was supposed to be an indication of actual disease of the urinary organs. This supposed distinction has attracted much attention on the Continent. Unfortunately Lépine and Cazeneuve have shown that the difference in the form assumed by the coagulated albumen depends much more on the liquid in which the coagulation is effected than on the albumen. The addition of an alkali prevents retractility, and conversely, an apparently homogeneous precipitate retracts into flocculi if a little acetic acid is added, no doubt, in consequence of the decomposition of alkaline albuminates. These conclusions have been confirmed by a series of observations made during the past winter by Dr. Rodet, of Lyons. In some urine from a patient with typhoid fever, which contained a small quantity of albumen, on two successive testings, he obtained in one flocculent and in the other non-retractile albumen. The reagent employed was that preferred by Bouchard, Tanret's solution, which consists of iodide of mercury dissolved in iodide of potassium and acidulated with acetic acid. The effect was found to be due to the amount of the reagent employed; a small quantity caused manifest retractility, but with a larger quantity this character was only observed in a slight degree after the urine had been boiled for one or two minutes. In a specimen of highly albuminous urine from a case of acute nephritis a flocculent precipitate was obtained when Tanret's solution was added, in whatever quantity; but if the urine was dropped into the heated reagent, the precipitate was non-retractile. On diluting the urine the retractility of the albumen was found to progressively diminish. When slightly diluted a few drops of the reagent yielded large flocculi, but they were much smaller with a larger quantity of the reagent. An extensive dilution abolished all retractility, whatever amount of the reagent was employed. No doubt it was the small quantity of albumen which occasioned the absence of retractility in the febrile cases observed by Bouchard, and gave him the erroneous idea that the character indicated a change in the blood and not in the kidney. It is clear that the differences in the character of a precipitate of albumen depend much more on the liquid in which it is formed than on the composition or character of the albumen itself. Indeed, it is very doubtful whether there is any physical property in the precipitate which can properly be described by the word retractility.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the announcement of the Dental Department of the University of Maryland, for the session of 1882–83.

——"Our Thirtieth Year;" annual address before the Kentucky State Medical Society; delivered by J. W. Holland, M.D. A reprint from the Louisville *Medical News*.

——"The Special Therapeutic Value of Hyoscyamine in Psychiatry." By C. H. Hughes, M.D., of St. Louis. Reprint from the *Alienist and Neurologist*, April, 1882.

——"Acute Dementia Occurring in an Old Man. Recovery after two and one-half months of treatment." By C. H. Hughes, M.D., of St. Louis. A reprint from the *Alienist and Neurologist*, April 1882.

——We have received the thirty-third annual announcement of the Woman's Medical College of Pennsylvania. The college has a large list of matriculants, and seems to be in a very flourishing condition.

——"The Opium Habit, its Successful Treatment by the Avena Sativa;" a paper read by E. H. M. Sell, A.M., M.D., before the New York State Medical Society, February 9th, 1882, and reprinted from the *Medical Gazette*.

——The Essentials of a Law to Regulate the Practice of Medicine in Indiana. A paper full of wise suggestions, read by Thad M. Stevens, M.D., before the Mitchell (Ind.) District Medical Society, in New Albany, December 28th, 1881.

——We have received the Catalogue of the University of Pennsylvania for 1881-2. Containing, as it does, one hundred and eleven pages, we note a striking difference between this substantial volume of '82 and the comparatively insignificant catalogue of '72.

——The "Home Treatment of the Insane," by Samuel Ayres, M.D., of Pittsburgh, Pa., comes to us as a reprint from the Pittsburgh *Medical Journal*. This is an interesting and instructive pamphlet, the perusal of which will amply repay the time it consumes.

——The History of Three Cases of Hip Disease in the Third Stage. By A. B. Judson, M.D., Orthopedic Surgeon to the Out-patient Department of the New York Hospital. Reprint from Illustrated Medicine and Surgery. This is a valuable and very interesting paper, well illustrated.

——Sanitary Survey of Indianapolis, Topography and Surface Geology, Water Supply, Disposal of Excreta, Cellar and Yard Filth, etc. This comes as a reprint from the *Transactions* of the Indiana State Medical Society, 1880, and is a pamphlet possessing peculiar interest to all who have any love for hygiene.

——We have received the report of the sixth annual meeting of the American Medical College Association, held at Cincinnati, May 16th, 1882. The tone of the meeting, and the spirit of the members present, indicated that the Association has entered upon a more hopeful future. Dr. W. W. Seeley, of Cincinnati, is President; and Dr. Leartus Connor, of Detroit, Secretary.

——"Rupture of the Eyeball in its Posterior Hemisphere, from a Blow in the Face." By Julian J. Chisolm, M.D., of Baltimore. "Two Cases of Malignant Tumor of the Sphenoidal Cavities, Implicating Vision." By Julian J. Chisolm, M.D., of Baltimore. These two papers, reprints from the Archives of Ophthalmology, have been received, with the author's compliments.

——"Operation for Radical Cure of Chronic Hernia." By Edward Von Donhoff, A.M., M.D., Louisville, Ky. This little pamphlet describes the author's operation, which in substance is as follows:—

First. The ordinary incision.

Second. The opening of the sac and reposition of the gut.

Third. Cutting away the sac within an inch from the ring, and when not too large (as in some scrotal hernias), dissecting out the distal portions.

Fourth. Closure of the mouth of the sac-neck, by means of strong, double sutures, entered through the skin three-quarters of an inch from the cut edge, thence passed through the sac-wall (both sides), a half-inch from its extremity, the needle making its exit through the opposite skin-flap. As many sutures will be used as are required to securely close the lumen of the neck, and will be quite firmly tied. (The remainder of the incision to be closed as ordinarily.)

Finally. The application of a firm, flat compress, moistened with water, and confined by a spica, will complete the operation.

It is intended, by the means advised, *to secure a broad, firm union between the cut end of the sac and the immediately overlying skin, and a union of the approximate sides of the lumen of the neck.* This accomplished, I think all future trouble from the hernia (?) will have been successfully warded off. If the distal portion of the sac be not removed at the time of the operation, it may be left for after consideration.

BOOK NOTICES.

The Physician Himself and What He Should Add to the Strictly Scientific. By D. W. Cathell, M.D., late Professor of Pathology in the College of Physicians and Surgeons of Baltimore. pp. 194. Baltimore: Cushings & Bailey. 1882.

This book has been prepared with the view of telling the young physician how to procure practice. While we do not believe in and cannot sanction physicians who advertise, no matter howsoever discreetly they may cover up their advertising tracks, yet since this volume starts out with the fundamental principle that it is necessary for the physician who desires to be successful to have a thorough knowledge of his profession; and since the advice that it contains counsels nothing that would be unbecoming a gentleman and a physician, therefore, can we recommend it to those young men who, though thoroughly competent, yet are commencing to despair of ever procuring a practice.

The Experimental Method in Medical Science. Second Course of the Cartwright Lectures of the Alumni Association, College of Physicians and Surgeons, New York. By John C. Dalton, M.D. pp. 108. New York: G. P. Putnam's Sons. 1882.

A more readable and interesting little volume one will rarely have the good fortune to hear of. It contains three lectures: Lecture I, "Galvani and Galvanism in the Study of the Nervous System." Lecture II, "Buffon and Bonnet in the Eighteenth Century." Lecture III, "Nervous Degenerations, and the Theory of Sir Charles Bell." They are all extremely interesting, but particularly so is the one which treats of the theories of Buffon and Bonnet. The leisure time of the busy practitioner could not possibly be put to better use than by the perusal of just such works as this.

Materia Medica and Therapeutics; Inorganic Substances. By Charles D. F. Phillips, M.D., Member of the Royal College of Physicians, etc. Edited and Adapted to the United States Pharmacopœia, by Laurence Johnson, A.M., M.D. Lecturer on Medical Botany, Medical Department, University of the City of New York. Vol. II. pp. 340. New York: William Wood & Co., 1882.

This volume constitutes the May number of Wood's Library of Standard Medical Authors. Vol. I has been already noticed.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

HOTBEDS OF DISEASE.

In this age of sanitary progress it behooves us to, and generally we do, look carefully for any causes of disease that may exist around us, and endeavor to remove them. But with the same experience as is met in other fields, it very often happens that while we recognize and make much of slight and trivial matters, we allow to continue unnoticed and unremedied some of the most serious and most fatal disease producing agencies. We make a great outcry against dirty streets, and rightly so; we complain of impure water, and justly; we object to the proximity of manufacturing establishments in which dead organic matter is used, and rightly. These are all potent causes of disease, and we must object to them and have the trouble remedied. But there is another terrible source of ill health, working insidiously (so far as the majority who do not see the evil are concerned), but surely all the time, poisoning the systems and sapping the health of those who fondly and delusively imagine that they are surrounded by all the conditions necessary for healthy and lengthy life.

In every large city that has attained any age will be found a section known generically as the "*slums*," in which are huddled together the vilest, foulest, most degraded and diseased members of the community. Very few of the better class of inhabitants ever see these sections, since they have no business in these neighborhoods. The inhabitants of the *slums*, men, women and children, are so disfigured, disgraced and deformed by the wretched, diseased lives they live, that, in truth, they can scarcely be called human beings. With but an exceedingly rare exception they are all drunkards; their whole lives are passed in a state of intoxication, and this condition is produced by the use of the most vitiated and poisonous liquor. Their food is the poorest and scantiest imaginable, nearly all of it procured by begging or theft. Morality is one of the "lost arts" among them, hence the most loathsome diseases are the rule. Indeed, the venereal wards of the pauper hospitals are filled with the most disgusting and repulsive patients from the slums. Water is not, by them, considered of any use in the world; their filth of body and clothes is something marvelous; you would wonder how any human being could possibly get so dirty. As a natural consequence of all this foulness the houses are absolutely saturated with disease germs, and I verily believe that PASTEUR could almost find bacilli of disease in the bricks of the sidewalks and the cobbles of the streets. The whole section, houses, streets, women, men, children, black and white, for they all live huddled together indiscriminately, the white woman with a black husband and vice versa, dogs, cats, atmosphere, everything and everybody are rotten, are reeking with disease.

In this section we have our *hotbed* of disease. From this nursery, under these favorable circumstances, are generated the elements of disease that are wafted by the winds throughout the city, to poison and disease the millionaire in his palace, who probably is ignorant that any such place exists. It is only necessary for one to walk through any one of these sections to believe firmly this statement. But the remedy!

Simple enough. Almost constantly some rich man is dying and leaving an enormous fortune to erect or endow some institution of learning. Education is one of our greatest blessings, and deserves much encouragement, but the prevention of disease and preservation of health is a more important consideration. Now, then, the following plan ought to be carried out by the city government, but if such is impossible of achievement, then should it be suggested to some wealthy philanthropist. The properties in this section should be bought and *demolished.* This would force the worthless and dangerous population away from their filth and squalor into a location much cleaner and purer, when, by judicious use of moral suasion, their repulsive, brutish natures might be elevated some little. Surroundings have much influence on the nature and mode of life of an individual, and it is to be greatly feared that no amount of persuasion can ever have any permanently good effect on a class of persons surrounded, as these wretches are, by disease, filth, gloom and misery. It is true, as has been said, that to many this state of affairs has assumed the relation of a second nature, and that they prefer such a life and surroundings. To a certain extent, this is true; they know no better life, and are seemingly content with what they have. But their very lives, their actions, all evince a sense of despair altogether incompatible with true contentment.

By resorting to some such measures as suggested a double good would be accomplished. These poor, miserable beings might be elevated and improved, while the general health of the city would undoubtedly be benefited.

THE ATROPHIC KIDNEY.

(*Nephritis atrophicans*).

A short time ago Prof. Biermer gave an interesting description of the atrophic kidney, at a meeting of the physicians in Breslau. We take the following from a report of the *Deutsche Medicinal Zeitung.*

Biermer describes the genuine atrophy of the kidneys as a special disease, distinct from *morbus Brightii.* The course of the malady is as follows: There does not exist a special etiology of the genuine atrophic kidney, but frequently exposure to cold, and especially wet feet, are mentioned as cause. The disease runs, from the beginning, an insidious and chronic course. In the first stage we generally find moderate albuminuria, polyuria and slowly progressing deterioration of the general nutrition of the body. Later two more stages may be distinguished: the second stage, during which the changes taking place in the heart and in the pulse become plainly apparent, but where the hypertrophy of the heart compensates for the disturbance in the kidneys; and the third stage, in which this compensation ceases and uræmic symptoms, besides an extreme emaciation bordering almost on marasmus, develop themselves. The malady may continue several years ere death sets in. The pressure of albumen in the urine is a *sine qua non* to establish the diagnosis; while generally the urine of the atrophic kidney is excreted in large quantities, of low specific gravity, comparatively poor in urea and other solid constituents, mostly free of sediment, and containing a changeable, though mostly small amount of albumen, and very little epithelium, and few casts. The polyuria is generally not connected with polydipsia. The hypertrophy of the heart is usually confined to the left ventricle and presents the concentric form, without dilatation. The pulse is tense; its frequency varying greatly. Palpitation is a rare symptom. Of great diagnostic value are disturbances of vision and positive signs on the retina. Disturbances of respiration are, perhaps, never absent during the course of this complaint. Brain symptoms might not develop themselves till the uræmic stage is reached, but even then they may be wanting till death takes place, which mostly happens under stupor or coma. Want of appetite and dyspepsia may be present or absent. Vomiting has its origin mostly in uræmia, especially when a frequent symptom. General disturbance of nutrition is never wanting. One might say that blood and fat dwindle away together with the kidney. This is one of the distinguishing marks by which

nephritis atrophicans is immediately recognized from harmless, functional albuminuria. A person whose urine contains albumen for a long time, and who does not become emaciated, but rather stout and corpulent, does surely not suffer from an atrophic kidney. The presence of dropsy proves that the case is not one of genuine atrophic kidney, but either one of secondary atrophy or that complications exist. An actually effective treatment of the disease is not known. Any diminution in the excretion of the urine has to be guarded against; astringents, therefore, as lead, silver, ergot or tannic acid, are to be avoided. To increase the quantity of the urine, scilla, digitalis, mineral waters and other mild diuretics as well as tonics are indicated. In the uræmic stage only the narcotics seem to be of any value.

Notes and Comments.

Glycerinum Boracis, for Chancres.

In the *Lancet*, Dr. George Thin relates some very interesting and valuable results derived from the use of the glycerinum boracis in the treatment of chancres. In the first case he describes, a man infects his wife, and for some time no treatment is resorted to. The sore continues to enlarge, and is finally cauterized several times, but without avail, and when Dr. Thin first saw the case, he found a sore, the size of a dime, on the side of the vagina, covered, except at the edges, with a black, sloughy-looking mass. The sore was kept constantly bathed in glycerinum boracis; the inflammatory action subsided, the surface became clean, and the ulcer healed without a bad symptom. While this treatment was going on, a little vesicle appeared on the fourchette, which burst and left a small chancre, which did not spread laterally, but eat down into the tissue for at least a quarter of an inch. The channel was plugged with cotton wadding soaked in glycerinum boracis, and it immediately commenced to heal from the bottom and was soon well.

In the second case there were four chancres on the glans penis, and phimosis supervened. Zinc ointment and black wash were applied, but the inflammation increased. Painting with tincture of iron improved them a little. Subsequently caustic was applied, which greatly increased the inflammation. Dr. Thin saw him two months after the chancres were first contracted, when he had phimosis, with considerable pain and swelling, and it was impossible to retract the foreskin sufficiently to see all the sores. One was seen to be covered with a dirty gray, membranous-looking substance. He was directed to insert, with a blunt probe, pieces of lint soaked in glycerinum boracis, so as to keep the glans and inner surface of the prepuce completely bathed in the solution. Five days afterwards the foreskin could be retracted completely, and all the sores looked healthy, and within ten days they were well.

The third case was very similar. He used this remedy, on the ground that, if the poison keeping up the inflammation was of a parasitic nature, it might be destroyed by the antiseptic properties of borax. His results were so satisfactory, that he proposes in the future to give it a trial in hospital gangrene.

Hemorrhage and Gangrene from a Carious Tooth.

In the St. Louis *Medical and Surgical Journal*, Dr. William A. Byrd reports the following case: He was called to see a boy between seven and eight years of age who was suffering from gangrene of the left side of the face and neck, accompanied with severe hemorrhage. The child was very anæmic, with the left side of the face swollen, with an opening that would admit the point of a finger, opposite the sub-maxillary gland, another in the meatus auditorius, and another in the mouth opposite to the outside of the first molar tooth; from all these openings was flowing a dark, very offensive fluid, mixed with arterial blood, and also, shreds of gangrenous connective tissue protruded from them. For some weeks the child had suffered from an offensive discharge from the left ear; and about two weeks before I saw him the first left molar tooth commenced aching and the jaw to swell. Subsequently a black spot appeared opposite the tooth, and at this spot the skin gave way, giving vent to a dark, very offensive discharge. The swelling from the ear and the tooth coalesced and the abscess broke into the ear and mouth, causing a profuse discharge from each. In a day or two blood was freely discharged from all three openings. The patient was etherized, and it was discovered that the bleeding came from so many points that it would be impracticable to secure all of them without too great a loss of blood and shock to the patient. It was, therefore, decided to ligate the common carotid, which was done with catgut. Through the incision a great quantity of gangrenous matter was removed as high

as above the zygoma and down nearly to the clavicle. The cavity was carefully washed out with a solution of boracic acid and packed with oakum soaked in eucalyptol and vaseline. He rallied well and seemed brighter, but sank again, and died on the second day. Dr. Byrd thinks that the carious tooth was the origin of the trouble, and that if it had been attended to in time the result would most likely have been different.

Gall Stones in an Infant.

Dr. A. Dunbar Walker contributes the following interesting case to the *British Medical Journal*. He saw a male child, three months old, who had been brought up entirely at the breast, and had always been healthy, excepting a slight attack of jaundice, a few days after birth. In the evening it commenced to cry, and continued to do so almost uninterruptedly for six hours, when a sedative mixture afforded a little restless sleep. The next morning a dose of castor oil was given, which soon caused an evacuation. The passage was healthy in appearance, but upon close inspection, three small ovoid bodies, dark green in color, and as hard as wax, were found. The larger one weighed two grains, the other two were much smaller. These substances seemed to consist of cholesterine; minute particles of the coloring matter of the bile could be detected here and there. This occurrence might account for the crying in many cases, and it would suggest the advisability of looking for these gall stones in the case of fretful children.

Corpus Luteum.

Before a recent meeting of the Obstetrical Society of London (*British Medical Journal*), a paper on the above subject was read. Two cases were described. The first was that of a prostitute, aged twenty-one, who died from prussic acid poisoning. In her ovary a fully ripe corpus luteum was found, although she was neither pregnant nor menstruating. The difference between the corpus luteum of pregnancy and that of menstruation was usually ascribed to the increased amount of nourishment received by the follicle in the pregnant state. In this case, he thought that prostitution was probably the cause of the increased nutrition and development of the follicle. The second case was that of a woman, aged forty-one, who died from gangrene of a uterine fibro-myoma. The ovary contained a true corpus luteum, and in other respects resembled the ovary of a pregnant woman. In this case, he thought the increased determination of blood to the part, in consequence of the fibroid, was the explanation of the size of the corpus luteum. The President said that it was important to have the view confirmed that a corpus luteum, having all the characters of that met with in pregnancy, occurred in women who were neither pregnant nor menstruating. He had seen such a corpus luteum in an aged woman, who was believed to be salacious, and he had dissected cases of pregnancy with complete absence of corpus luteum.

Water of the Sacred Springs at Mecca.

The *Journal d' Hygiene* gives the following extract from a letter of Dr. Frankland, regarding the water of the springs at Mecca, regarded as sacred by the Mohammedans:—

"This particular sacred spring is situated at Mecca, and the water is sent in large quantities to the various Mohammedan nations; certain princes have, indeed, a special envoy to send them, each year, a number of bottles of water from the spring. Dr. Frankland says he had the curiosity to make a complete analysis of the water, and found it to be a veritable sewer water, seven times more concentrated than that of the London sewers, for it contains not less than 579 grains of solid matter per gallon.

There is not, probably, a more active means of propagation of epidemics through the Eastern nations.

Removal of Foreign Bodies from the Ear.

In the Detroit *Lancet*, Dr. A. F. Kinne, after pointing out the defects in all the existing instruments and methods for the removal of foreign bodies from the ear, describes a simple instrument, devised by himself, for this purpose, which has answered admirably. It really consists of a minute, sharp-pointed, tenaculum-shaped hook, on the reverse end of which there is a small, blunt hook, for the removal of foreign bodies from the nose. In order to remove a foreign body that has been pushed through the tympanum into the deeper recesses of the ear, it may, in some cases, become necessary to detach the auricle before an instrument can be brought to bear upon it. As a justification for this operation, he relates the following case:—

About twenty-five years ago, I was called to a well grown boy, whose ear had been torn off, close to his head, by a wagon wheel. The wound was ragged and dirty, and the bystanders

thought the ear "no good;" but the skin in front of it was not torn through, and I decided to attempt its restoration, and succeeded. I pinned it on with cambric needles, annealed and curved. And, mindful of the danger that the ear might slough, when I passed my ligature around the ends of these, I sought to bring the torn edges into close apposition, without drawing it tightly enough to interrupt the local circulation.

Of course, very complete access to the middle ear is gained by detachment of the auricle. And, as to the feasibility of the operation, two questions, and the only ones of any consequence, were settled well enough by the results of this accident. First, an ear will grow on again, even if the incisions by which it is detached are not smooth and clean; and second, the resultant scar is of no consequence, especially when it is located behind the ear.

Prevention of Diphtheritic Infection.

M. Hager, in the *Pharm. Centralblatt.*, recommends lozenges, composed after the following formula, to persons who are exposed to the infection of diphtheria:—

℞.	Ceræ alb.,	ʒ v	
	Colophon.,	ʒ iss.	M.

Melt together, and then add—

℞.	Tolutan. bals.,	ʒ iiss	
	Pulv. aromat.,	ʒ iss	
	Sacch. alb.,	ʒ v	
	Ac. benzoic.,	ʒ iss–iiss.	M.

Reduce to fine powder, and aromatize with—

℞.	Ol. cinnamomi,	♏x	
	Creasot.,	ʒ j.	M.

After the mass has cooled divide into 100 pastilles.

One of these lozenges should be very slowly masticated, four or five times daily.

Treatment of Fissure of the Anus Complicating Chronic Metritis.

Fissure at the anus is frequently observed in women affected with parenchymatous or endo metritis. The most frequent cause for this affection is the chronic congested condition which exists about the anal region, as well as in the uterus and its appendages. In connection with this, there is almost constantly obstinate constipation. Surgical treatment in such cases is not always of benefit, particularly when the fissure has not induced contracture of the sphincters.

Two forms are observed in practice: In the first the fissure is of old date, and its borders are hard and callous.

In such a case, M. Chéron, in a recent number of the *Rev. med. chir. des maladies des femmes*, recommends that massage over the part, with the pulp of the index finger, should be made every day; then he places in the fissure a small metallic cylinder, connected with the negative pole from two elements of the pile, the positive pole having an electrode as large as possible.

Five minutes' application is sufficient to produce a modifying chemical action without causing any pain.

A calming unguent is applied each evening to the fissure:—

℞.	Ext. digitalis,	ʒ ss	
	Ext. belladonnæ,	gr. xvss	
	Adipis,	ʒ j.	M.

A dozen applications generally suffice for cure.

In the second form there are no indurated borders, but the parts are painful and sensitive when touched. In such a case iodoform is recommended:—

℞.	Iodoform,	gr. xvss	
	Balsam Peru,	ʒ j	
	Adipis,	ʒ j.	M.

If there is spasm of the sphincter muscle, gradual dilatation may be established by the introduction of a bivalve speculum, once every four or five days.

Dental Tumor of Jaw.

In the *Canada Medical Record*, Dr. C. E. Nelson relates the case of a girl of 15, who was suffering from a large tumor of the lower jaw, which had been steadily growing for about six months. For four months the pain had been so severe that morphia had to be used continuously. A distinguished surgeon diagnosed malignant disease, and advised immediate removal of the tumor, along with a considerable portion of the jaw bone. The day before the proposed operation, a dentist was consulted, who, after a careful examination, came to the conclusion that the tumor was not malignant, but was caused by the presence in the jawbone of several of the second teeth, which had not yet been evolved. The tumor was freely opened, a quantity of extremely fetid matter was discharged, and the pain was instantly relieved. A probe revealed that the anterior surface of the bone below the incisors had been absorbed, and at the bottom of the cavity so formed several hard bodies could be felt imbedded in the bone. The cavity was cleaned out and packed with lint soaked in a solution of chloride of zinc. Antiseptic applications were used regularly, but the wound continued to discharge a thick, black and very fetid fluid. By the end of six weeks three

teeth could be distinguished, viz., the right canine and two right lateral incisors, and at the end of three months these teeth were extracted through the opening made when the tumor was lanced. A year afterwards the cavity had filled up and the jaw returned to its normal shape.

Danger from Toy Paint Tablets.

As these small boxes of paint tablets are sold at very low prices to children at all the toy shops, it is right to call the attention of the profession to their dangerous composition. We read in a recent number of the *Revue d' Hygiene et de Police Sanitaire*, that a child was recently poisoned in Epinal from eating a green colored tablet. The central commission of hygiene procured a number of tablets from the toy shops of Epinal, and on examination found them to consist of sulphate or carbonate of calcium and an arsenical composition (either Scheele's or Schweinfurt's green), one specimen containing the enormous proportion of 20 per cent. of the arsenical color.

Certain it is that colors are made which are innocuous, but not at the price these small boxes are sold, and the matter should receive further and careful attention.

Epidemic of Tinea Tonsurans.

At the last séance of the Conseil d'Hygiene et de Salubrité of the Seine Department, M. Hillairet presented a very interesting report on the prevalence and rapid spread of tinea tonsurans in the 11th arrondissement of Paris. It was first particularly remarked in an orphan asylum, where it was imported by a day scholar; in a few days nineteen of the inmates contracted the disease. Energetic measures were immediately set on foot to arrest its ravages; the infected children were isolated in a special dormitory and not allowed to eat or play with the other inmates of the school. The treatment advised by M. Lailler consists in repeated epilation, frequent washing with castile soap, and applications with ointment containing turpeth mineral; in connection with this the children are obliged to wear continually a skull cap.

M. Hillairet, in attempting to trace the origin of the disease, found that there existed a number of cases among children and adults in the Charonne quarter, including several cases in the schools. As the disease is propagated with extreme facility, and requires, for complete cure, assiduous and long-continued treatment, M. Hillairet recommends careful search into the conditions of the arrondissement, and isolation as far as possible of the individuals affected. Without such precautions he fears a rapid spread of the evil to surrounding sections of the city.

In connection with the report, it is interesting to note that there is a corps of "epileurs" attached to several of the hospitals of Paris, demonstrating that such diseases are rather common.

Treatment of Scarlatina.

Dr. Lervis, we read in a recent number of *Le Progrès Médical*, recommends digitalis to limit the acceleration of the pulse in scarlatina and also as a prophylactic against renal complications.

The infusion of digitalis should be given as soon as possible after the début of the malady, and continued up to the third week. The whole body should be anointed with oil twice daily until desquamation is completed.

To prevent the development of diphtheritic angina he recommends the following potion:—

℞.	Potass. chlorat.,	ʒ j
	Tr. ferri perchlorid.,	ʒ ij
	Glycerinæ,	ʒ j
	Aquæ destil.,	ʒ viij. M.

A teaspoonful should be given every half hour.

Billroth on Removal of Cancer.

In the course of a letter from Billroth to Dr. Wywodzew, concerning the nature of the last illness of Pirogoff (a translation of which appeared in the Boston *Medical and Surgical Journal*), this great surgeon, discussing the propriety of operative interference for the relief of cancer of the jaw, from which Pirogoff was suffering, says: "Interesting and instructive as the results of the microscopic examination are in such cases, and the etiology of the development anatomically so well illustrated, the diagnois of cancer in this case would not have influenced me to an operation. A man over seventy, of active mental habits, yet showing all the signs of bodily marasmus, with a cataract in each eye, etc., has no possible chance of withstanding an operation such as I would have been compelled to make, even in order to prevent a recurrence for a very short period of time. My experience, of thirty years, as a surgeon, has taught me that those sarcomata and carcinomata which originate away back on the upper jaw can never be radically removed by operative interference, when one operates so as to provide for the probability of the patient surviving the operation. One is so disturbed in this region, partly by technicalities, part ana-

tomically, that a true and total extirpation cannot be made, save in those isolated cases where one has to do with an encapsulated tumor. I am no longer the bold, unterrified operator I used to be."

Manner of Administering Tannin.

Tannin, given by the mouth, either in powder or in simple solution, often gives bad results; sometimes having no effect, and often causing pain or inflammation of the stomach and intestines. At the polyclinic of Leipsic, this is avoided by the use of the following mixture, of agreeable taste, yet astringent, and easy taken by children; it is an albuminate of tannin:—

℞.	Tannic acid,	ʒj	
	White of egg,	ʒiij	
	Water,	ʒiij.	M.

While adding the white of egg, the mixture should be continually agitated.

Treatment of Sycosis.

According to M. Bouchut (*Jour. de Connoissances Med.*), sycosis may sometimes be cured without epilation, by means of applications, made morning and evening with an unguent, of which creasote is the active element. He recommends the following formula:—

℞.	Creasot.,	♏xx ad fʒss	
	Zinci oxid.,	ʒiss	
	Ung. simpl. benzoat.,	ʒj.	M.

After each application of the ointment the affected parts should be covered with oiled silk.

Correspondence.

Dialysed Iron in the Treatment of Arsenical Poisoning.

Ed. Med. and Surg. Reporter:—

It is not my intention to enter into an exhaustive paper on the subject of Arsenical Poisoning, but simply, as a duty, to lay before the profession what I consider a most valuable aid, the administration of dialysed iron. In the smelting of lead and silver ores, one of the worst features is the constant inhalation of arsenical fumes. When first employed by the Alta Montana Company, to take charge of their hospital, a number of cases of arsenical poisoning came under my observation, and they were the more difficult to treat on account of their complication with "leading." I tried the various remedies recommended for such cases, with but poor results. At times I felt that old saying, "Throw physic to the dogs," was but too true and applicable. At last I was led to try dialysed iron, and was met in all cases with most gratifying success, as is evidenced by the following cases:—

Two carpenters were engaged in roofing a portion of the smelting building, and were in such a position that the wind carried the fumes into their faces. Some workmen below noticed one of the men swaying to and fro, and about ready to fall, while the other was laboring hard to reach the ground. They were helped to the hospital, and were suffering with severe pain in stomach and bowels, nausea, vomiting, vertigo, and with a profuse "nose-bleed," tremor in lower limbs, and almost prostration. A wineglassful of dialysed iron was given immediately. The nausea ceased, and at the end of one hour the men were able to walk to their cabins, carrying with them a bottle of the iron, to be taken in drachm doses every half hour. At the end of twenty-four hours they complained only of weakness, such as would result from a severe diarrhœa. The second day they resumed work, entirely free from all pain and effects of the arsenic. A number of men employed about the smelting furnace, and especially in dipping the molten lead, have been apparently prostrated, from the effects of the fumes, and were in every case relieved by dialysed iron. A mild purgative was given within twelve hours. I have recommended, and, indeed, insisted on, every man who is exposed to the arsenical fumes, taking a dose of the iron daily. The consequence has been, that we have had but one case of poisoning needing hospital treatment, and this one insisted that his case was one of "indigestion and dyspepsia," and would take nothing till compelled to enter the hospital, where, under the administration of dialysed iron, he speedily recovered.

In the past two years, I think I am safe in saying that fully two hundred cases of arsenical poisoning have been cured in this camp by dialysed iron. I could cite any or all of them, with symptoms, treatment etc., but I think it unnecessary, as they so nearly resemble those already mentioned; suffice it to say, that all experienced the nausea, griping, vomiting, muscular tremor, etc. I have given the iron, in half-ounce doses, three times daily, with no constitutional disturbances whatever, even after ten and often twenty days administration. The teeth are not discolored, bowels not constipated, and digestion not deranged.

The men have learned its virtues, and come regularly with "please fill my iron bottle again." They will not do without it, any more than an Irishman will do without his "salts and senna." It has saved many a man his wages and many a day of sickness. In fact, I feel convinced that this preparation is indispensable where men are liable to inhale the fumes of arsenic.

Without a remedy of this kind, I am satisfied no man, however strong, could inhale the fumes incident to smelting, where the ores contain arsenic, and stand it more than three or four days. I can fully and confidently recommend this preparation of iron to the profession, and even to foremen of smelting works where there is no physician, for it is harmless and in valuable. An ounce of prevention is worth a pound of cure;" or a "pound of cure," is worth infinitely more to a company, than are hospitals full of men poisoned with arsenic. Our hospital has been built, medicines bought, physicians

and nurses paid, and accommodations for thirty beds provided, inside of two years, by a small monthly assessment on each miner and laborer employed by the company, and all are satisfied; none more so than the smelter hands, who can and do get a "bottle of that iron," and keep at work.

The preparation which I have used, and to the good effects of which I can testify, is Wyeth's, of Philadelphia. A. M. Bullard, M.D.

Wickes, M. T.

Vaccination and Revaccination.

Ed Med. and Surg. Reporter:—

On July 12th, 1881, I vaccinated Mrs. Sarah A. W., and her two children, William and James H., with Chambersburg virus. The vaccinations of all of them took, apparently, satisfactorily. The three had also been vaccinated in their infancy, the marks of which were still observable. William contracted smallpox in its hemorrhagic form, which terminated fatally, August 12th, 1881. Shortly after the death of William the mother and her servant girl took varioloid. James H. escaped. On April 6th, 1882, Sarah A. W. was taken sick, followed by an eruption simulating that of varioloid, but owing to the fact of her having had varioloid previously, I was uncertain as to my diagnosis; but the prodromic symptoms, together with the eruption, undoubtedly pointed to a case of varioloid.

This brings us to the question as to whether one successful vaccination is a preventive of smallpox, or of its modified form? I believe, in the majority of cases, it is. It is a well known fact, however, that an attack of smallpox itself does not protect, in exceptional cases. the same person from a second attack. A patient has come under my observation who had suffered with confluent smallpox at two different times; the interval between the two attacks was thirty years. One case has also come under my observation, in which vaccination took perfectly well, notwithstanding that several years previously she suffered with varioloid. Now, if neither an attack of smallpox, nor of its modified form, varioloid, in some persons, is a preventive against a second attack of smallpox, or of its modified form, how much less, then, can one successful vaccination be a preventive of the disease? I believe, therefore, that the only safe plan of vaccination as a preventive of smallpox, is by repeating the vaccination with pure vaccine several successive times, at intervals of a month, until there is no longer any more predisposition in the persons so vaccinated to either vaccinia or smallpox. Had William and his mother been vaccinated each a second time, smallpox in the former and varioloid in the latter, I have no doubt, would have been prevented, the same as it was in the case of James H. John M. Batten, M.D.

Pittsburgh, Pa.

Does Vaccination Protect.

Ed. Med. and Surg. Reporter:—

Dr. Beggs, in the Reporter, for May 6th, asks some pertinent questions in regard to vaccination. From my observation I could answer some or all of them, not so satisfactorily, perhaps, as by some facts from personal experience. My father's older brothers were inoculated with smallpox matter, according to the fashion of their time, and had the disease in a modified form. My father, being younger, was vaccinated, as he came within the time of that discovery, in his sixth or seventh year. When about fifty, one of the neighbors was sick, and father was with him much of the time. It was pronounced a case of varioloid, and a child in the family had the disease severely. Father saw numerous cases after that. His health was as good as any of his family during life. He never had any symptoms of variola. When seven or eight years old, I took some vaccine matter from a good looking pustule on a school girl's arm, and scratched it into my wrist. It "took," and worked characteristically. I have generally had good health since, and never a sign of skin disease. I have never been revaccinated. I have been in the practice of medicine for twenty years, and but few of them have passed that I have not had cases of smallpox to treat. Have seen it in its worst forms, and never had a symptom of the disease. My vaccination has protected me for forty years. Not long ago I took my little daughter into the buggy, to answer a call a little way out of town. We drove up to the fence, and getting out, walked up to the house and went in. It was close and dark, and when I could see my patient, I found him in the stage of pustulation of smallpox. The little girl had taken hold of the man's hand. I did feel some trepidation; she is four years old. and had been vaccinated a year ago, with bovine virus matter. The time has passed for any signs of the disease. I expect she will be safe from its contagion all the rest of her life, if bovine vaccination is as good as humanized lymph, and she follows the example of her father and grandfather. Will some one else give their personal experience.

P. J. Farnsworth, M.D.

Clinton, Iowa, May 12th, 1882.

News and Miscellany.

Fourth Annual Congress of the American Laryngological Association.

Held in the Hall of the Medical Library Association, at Boston, on June 12th, 13th, 14th.

The President, Dr. F. I. Knight, of Boston, in the chair. Twenty-eight members present.

The first day's session was opened by an address of welcome, by Dr. S. W. Langmaid, of Boston.

The President then delivered his annual address, in which he called attention to the importance of laryngology, and the fact that this branch of medicine had received more attention within the past year, in all the medical schools of the country, and dwelt upon the great advantage derived by the general practitioner from the use of the laryngoscope. He entered more fully into the question of medical education, and especially the advantages derived by

the student from practical, clinical teaching of those branches in which personal observation is necessary. He then presented a plan for the practical teaching of laryngology, and said that the head of the department should give daily instructions for at least six weeks, in a room which could be darkened, and at the same time large enough to accommodate twelve students and as many patients, without crowding. It was his experience that these courses were given in rooms too small for the purpose, and consequently, the air in them became so vitiated that work could not be carried on with comfort in them. He concluded his address with the advice to the Association to raise the requirements of membership in the Association.

Dr. Elsberg then read an interesting paper on "Paralysis of the Vocal Cords," in which he gave a very clear and comprehensive classification of the different forms of paralysis, and also advocated a new nomenclature for the muscles of the larynx. He stated that unilateral paralysis was more common than bilateral, and that certain muscles were more prone to be affected than others. He also showed that spasm of the glottis might be present in such cases, and even alternate with the paralysis, sometimes necessitating tracheotomy.

Dr. Bosworth, of New York, said that he could see no advantage in the new nomenclature of the muscles of the larynx, and that in his opinion the classification prepared by Dr. Mackenzie, of London, into adductors and abductors of the cords, was so simple and comprehensive that he would prefer it to all other classifications. He also entered into the causes of the paralysis, and stated that they were either due to neuropathic or myopathic changes, and the latter were always caused by inflammatory infiltration in the muscular tissue.

Dr. Seiler concurred with Dr. Bosworth in preferring the old nomenclature, and objected to the function ascribed by Dr. Elsberg to the thyro-arytenoid muscle, viz.: that this muscle was a straightener of the vocal cords, and said that, owing to the peculiar insertion of the fibres of this muscle into the cords the latter must be drawn away from each other, and must be relaxed by the contraction of this muscle, thus making the edges of the cord concave.

Dr. Roe, of Rochester, reported a case of abductors of the cords, in which later brain lesions showed themselves.

Dr. Hartman, of Baltimore, reported a similar case, also due to central nervous disturbance.

Dr. Morgan, of Washington, said that double voice sometimes is produced by paralysis of the vocal bands; one of the sounds being produced by the membranous portion of the glottis, while the other is produced by the cartilaginous portion.

In closing the discussion, Dr. Elsberg said that he did not insist upon the adoption of his new nomenclature, but that he had found it more convenient than the old one. His reason for calling the thyro-arytenoid muscle a straightener of the vocal cords was, that when that muscle was paralyzed the cords were curved.

A paper sent by Dr. Glasgow, of St. Louis, on Laryngeal Asthma, was then read by Dr. Seiler. In this paper the author reported a number of cases in which asthma had co existed with laryngeal inflammation, and had been cured or greatly relieved by local treatment of the laryngeal mucous membrane. He came to the conclusion that in every case of asthma the larynx should be examined, and that if inflammation was found there it should be treated, for there were many cases of this affection which depended solely upon laryngeal irritation.

Dr. Jarvis, in discussion, reported two cases of hyperæmia of the cords complicated with asthma, which were relieved by local treatment.

Dr. Seiler said that he could readily understand how laryngeal irritation might produce asthma, when other peripheral irritations would produce a like result. He called attention to the fact that chronic inflammation of the larynx however, was, in many cases, due to nasal stenosis, and that the same cause, the mouth breathing, which produced the laryngeal irritation, might also directly cause the asthma.

Dr. Robinson, of N. Y., said it was an old fact that nasal obstruction was a cause of asthma, also that laryngeal irritation produced a like effect, but it was a difficult task to always locate the irritation in the larynx. Asthma was always due to organic lesion in the bronchial tubes, and he, therefore, was opposed to calling these cases laryngeal asthma.

Dr. Roe said that asthma might be due to irritation anywhere in the respiratory tract.

Dr. French, of Brooklyn, then exhibited some photographs of the laryngeal image taken by means of the laryngeal mirror in the living subject.

Dr. Morgan said he had made several ineffectual attempts to photograph the laryngeal image, but had not succeeded to his satisfaction. But that he had seen, several years ago, some made by Mr. Sleins, of Germany, which were tolerably good.

Dr. Elsberg said the difficulty was, that on account of the different planes in which the parts of the larynx were situated, all could not be brought into focus.

Dr. Seiler said that ten years ago he had tried to photograph the laryngeal image, but had failed, for the reason pointed out by Dr. Elsberg, and said that even if a good photograph could be obtained in a person accustomed to the mirror, it was impossible to photograph the larynx of a patient so as to obtain the pathological changes of the image, and this was the only utility of the process, in his opinion.

The session then adjourned to the afternoon.

AFTERNOON SESSION.

The first paper read was by Dr. Delavan, of New York, on

The Question of Hypertrophy of the Osseous Structure of the Turbinated Bodies, Practically Considered.

He said the design of this paper will be the establishing and the practical consideration of the following proposition, viz.: *The turbinated bones may, under proper conditions, undergo marked hypertrophy.* The opinion generally accepted upon this important question seems well set forth in the following paragraph, quoted

from a recent standard work upon "nasal catarrh." *

The author says: "The term hypertrophy of the turbinated bones is a faulty one, for the reason that real hypertrophy of these bones very rarely exists. Sometimes, indeed, it is true that one or more of them have become softer, more spongy, and more voluminous than they are in a perfectly healthy nose, but these are infrequent cases, and the very general rule is scarcely less true, *i. e.*, that hypertrophy is confined to the mucous membrane and submucous layer which cover these structures."

That this view is erroneous must be admitted, when due consideration is given, 1st, to the theoretical reasons which weigh against it, and, 2d, to the strong array of clinical evidence to which it is opposed.

1st. Theoretically, the process of hypertrophy in general may occur in almost any tissue of the body. Hypernutrition is, of course, the occasion of hypertrophy in bone as well as in other tissues, and to such structural changes the bones of the skull are particularly liable. To quote the familiar words of Sir James Paget: "Hypertrophy of bone presents itself in many interesting cases. It is usually a secondary process, ensuing in consequence of a change in a part with which some bone is intimately connected. Just as in their natural development and growth the bones of the skull are formed in adaptation to the brain, and those of the limbs are framed to a fitness of the action of the muscles, so in disease they submit in their nutrition to adapt themselves to the more active parts." †

The turbinated bones are not formed until a late period in the development of the fœtus. Indeed, "the inferior turbinated bone is ossified from a single centre which only appears at birth." ‡

This tardy appearance would imply considerable activity of development later in the history of the child, and it is not impossible to believe that in some cases there should occur an actual overgrowth. Again, although the condition of hypertrophy is antithetical with that of atrophy, there is no part which, being susceptible of one, is not also susceptible of the other. Atrophy of the turbinated bones, in the affection known as atrophic catarrh, is commonly met with and universally conceded to exist. Therefore, under conditions of nutrition opposite to those which characterize this disease, there should result the opposite condition of growth, namely, hypertrophy.

The probability of this result is greatly increased when we recall the peculiarly intimate relation which exists between the mucous membrane of the turbinated body and the bone, through the medium of the membrana mucosa, which not only forms a fibrous network for the support of the blood vessels, etc., but actually passes into the periosteum, the characteristics of which it more nearly resembles. Any increase of the blood-supply to the turbinated mucous membrane would be communicated, without doubt, to this periosteum in far more than the ordinary measure, and the nutrition of the bone proportionately increased. The conditions favorable to hypertrophy of the turbinated bone would seem to be—

1. Unusual space in the nasal fossæ.
2. Long continued hyperæmia of the structures investing the bone.
3. The existence of the above conditions during the period of greatest constructive activity.

It is an established fact that the too free inspiration of air through the nares will produce turgescence of the nasal mucous membrane, and where long continued, chronic hyperæmia. Persons, therefore, whose nasal cavities are unusually wide, are commonly the subjects of catarrh. In the normal nasal chamber the erection of the turbinated corpora cavernosa is limited by the boundaries of the nasal cavity. The greater the possibilities for expansion, and the more the exposure leading to congestion, the less likely are the soft parts to return to their normal conditions of size and nutrition. And, of course, the greater the hyperæmia of the soft parts, the greater the hypernutrition of the bone. With the above conditions occurring early in the history of the patient the hypertrophic process would go on, not suddenly and rapidly, but slowly, and in the course of the regular growth of the individual, not attaining its maximum until the adult period.

In the vast majority of instances the conditions which would furnish these factors would be congenital, and they would be found:—

1. In cleft palate.
2. In deviation of the nasal septum.

This first condition, however, is comparatively rare, and need only engage our attention by way of illustration.

Congenital *deviation* of the *septum*, on the other hand, is of frequent occurrence, and it is in this condition, theoretically speaking, that the largest proportion of cases of turbinated hypertrophy would appear. Of course, deflection may be produced at any time of life in a previous healthy septum; for example, by fracture or dislocation of its bone or cartilage, by pressure from an intra-nasal growth, etc. These instances, however, are unusual, and form the exception to the rule.

Reasoning by exclusion, therefore, the congenital origin of a large proportion of cases of deflection of the septum seems evident.

As will appear later, the middle turbinated bone is the one most frequently enlarged, and, since the septum is in a plastic condition until some time after birth, the question naturally arises, is the turbinated hypertrophy due to the deflection, or is the deflection due to the hypertrophy? If the turbinated bone was enlarged at an early date, why would it not, by crowding against the septum, force it beyond the median line, and thus become, not the result of the deflection, but actually its cause. This seems improbable, for two reasons: first, because nature is rarely asymmetrical, so that enlargement of one turbinated bone would probably be met by a corresponding enlargement of its fellow; and second, because the hypertrophied bone is almost invariably found opposite the point of

* "Nasal Catarrh," Beverly Robinson, p. 88, 1880.

† "Lectures on Surgical Pathology," Sir James Paget. Lindsay and Blakiston, 1865, p. 73.

‡ "Sharpey and Quain," vol. i, p. 72.

greatest concavity of the septum, in which position the opportunities for expansion are present in the most marked degree.

2. Turning now from theoretical considerations to the practical demonstrations of the main proposition, we desire to offer some anatomical and clinical evidence based upon direct observation.

About two years ago, while dissecting the nasal fossæ in a specimen which chanced to come into the Pathological Laboratory of the New York Hospital, the writer observed three points:—

1. There was well-marked deflection of the septum.

2. The side toward the concavity of the septum was completely occluded by the middle turbinated body.

3. Upon removing the soft parts from the middle turbinated bone, the bone itself was found to be in a condition of unquestionable hypertrophy.

The importance of this condition at once suggested itself, and its further investigation was immediately begun. To this end the museums of Washington, Philadelphia and New York were visited, and careful search for illustrative specimens made in the following craniological collections:—

	Crania.
Smithsonian Collection, Army Med. Museum, Washington, containing	4000
Academy of Natural Sciences, Phila.	2000
Wistar and Horner Collection, "	260
Wood Museum, Bellevue, New York	100
Hyrtl's Collection, College of Physicians, Philadelphia	140
	6500

In all these collections but the last, the crania were derived from every variety of source, and were in all stages of degeneration, so that the bony appendages of the nasal cavities were in most instances destroyed and the specimens unfit for our purposes. Far different was it, however, in the case of the splendid and unique cabinet of Professor Hyrtl, purchased by the Mütter fund for the College of Physicians, Philadelphia, and intended to exhibit a typical representation of every nationality in Europe. The specimens were derived indiscriminately from persons of at least average good health, and with no reference whatever, of course, to existence of any nasal deformity. In nearly every instance in which hypertrophy was observed, it was confined to the middle turbinated bone of the wider nares, which singular predilection can only be explained on the ground that, as this turbinated body occupies the position directed toward the greatest concavity of the deflected septum, its opportunities for expansion during life are greater than those of its fellows. In the case of a very few specimens the middle turbinated bones were broken.

The hypertrophy was, as a rule, symmetrical, extending throughout the whole antero-posterior course of the bone in about the same relative degree. It had about it nothing whatever of the nature of an exostosis, but the bony plates were of the same relative thickness as in the normal organ, the whole resembling a natural turbinated bone magnified in size. In some instances, however, they were notably thinner than normal, and the condition of general, symmetrical hypertrophy was by no means constant, the enlargement seeming rather to follow the course of the deflected septum.

An examination of the collection developed the following extraordinary statistics:—

Of the whole number of specimens	140
There was deflection of septum in	$18 = 12\frac{4}{5}$ p. c.
Of these 18 there was	
Hypertrophy of the middle t. b. in	$11 = 7\frac{4}{5}$ p. c.
Absence or atrophy of " "	$7 = 5$ p. c.

Or,

Of the whole number of cases of deflection of septum	18
There was hypertrophy of the m. t. b. in	$11 = 60$ p. c.
There was absence of, or atrophy of, the m. t. b. in	$7 = 40$ p. c.

It will thus be seen that in the above collection more than one-half of all cases of deflection of the septum showed hypertrophy of the middle turbinated bone. The actual percentage of cases of hypertrophy is probably much greater than 60 per cent., as in the several specimens in which the turbinated bones were missing, the middle turbinated bones were, without doubt, as judging from the perfect specimens, larger than normal. During the course of the above examination *exostosis of the septum* was not found in a single instance. In a number of cases the writer has demonstrated the presence of this bony hypertrophy in the living subject, by sounding, as it were, the enlarged mass with a fine needle, and observing the depth at which its point was arrested. Instead of entering the mass for some distance, as would be expected, it will frequently impinge upon bone at a point comparatively near the surface.

The figures above given will surprise those who believe that stenosis in deflection of the septum is caused by hypertrophy of the soft tissues alone, and that absolute relief will follow the removal or destruction of the redundant mucous membrane. Indeed, in several specimens examined, the middle turbinated bone had approached so nearly to the septum that it was scarcely possible to sweep a probe between them, and the occlusion was almost as complete as it could have been during the presence of the soft parts. No attempt at relieving the resulting occlusion simply by the removal of the mucous membrane could have succeeded. In such a condition the free inspiration of air must have been greatly reduced, while the olfactory region was shut off most completely, and all perception of odors thereby lost. The results of nasal stenosis, and the necessity for its relief, have been ably described by many excellent writers, and need not here detain us. Heretofore operative efforts have been directed solely to the relief of the occlusion of the narrower nostril. For this three general methods have been proposed—

1. Removal of the mucous covering of the convexity of the septum.

2. Removal of the mucous covering of the

convexity of the septum, together with the underlying bone.

3. Boring bodily through the nostril by means of the dental engine.

In all these operations the condition of the enlarged turbinated bone of the opposite side has been unrecognized. Any operation for rectification of the deflection of the septum would, in such a case, only result in making the occlusion of the wider nostril more complete than before, and since the nostril toward the convexity of the septum is often more pervious than the other the operation would fail of its object. Removal of the turbinated bone itself, entire or in part, is therefore essential. As to the propriety of the operation, there is no reason, anatomically or surgically speaking, why it should not be performed. In a recent article,* by so eminent an authority as Morell Mackenzie, it is warmly recommended, and he refers, for his support, to Valsalva, Fergusson, and Pirogoff, adding: "I have myself frequently removed portions of the turbinated bones without seeing any evil result follow, and it appears to me extremely doubtful whether any bad effect could result from the removal of a portion of one of them."

From what has been proven with regard to the anatomical conditions in deviation of the septum complicated with hypertrophy of the middle turbinated bone, we feel justified in asserting that the rational and scientific plan of operation for its removal would be as follows:—

1. Removal of the obstructing middle turbinated bone of the wider nostril, allowing at the same time, if possible, a remnant of the organ to remain, sufficient for the performance of its normal physiological function.

2. Straightening the deflected septum.

By this means will be obtained, we believe, all of the ends most desirable for the relief of this most uncomfortable and injurious condition.

CONCLUSIONS.

1. Hypertrophy of the turbinated bones is of frequent occurrence, especially in connection with deviation of the nasal septum.

2. Nasal and catarrhal conditions, stenosis, resulting from such hypertrophy, can be permanently relieved only by removal of the bone itself.

3. Removal of the bone is a justifiable operation.

4. In the existence of such hypertrophy no operation for the restoration of a deviated septum should be resorted to until after the removal of the opposing turbinated bone.

In the discussion following Dr. Seiler said he had seen several cases of hypertrophy of the turbinated bones, and that they all had been bladder-like expansions of the bony tissue, into which the drill of the dental engine entered very easily.

Drs. Ash and Bosworth, of New York, agreed with the writer, the latter stating that he had seen a number of cases, but had found that the tissue overlying the bone had also been hypertrophied. Dr. Ingals said that he was of the opinion that hypertrophy of the turbinated bone caused deflection of the septum, and not, as the writer had stated, that the reverse was the case.

Dr. Bosworth said all his cases had been on the right side.

Dr. Jarvis said that hypertrophy of the turbinated bones was very rare. Also, that the presence of hypertrophied turbinated tissue would produce thickening of the septum, which might be confounded with deviation of the septum.

Dr. Seiler said he was in the habit of measuring the thickness of the septum by means of a pair of callipers, and thus was at once enabled to make a differential diagnosis between localized thickening and true deviation.

Dr. Deblais, of Boston, said he had found deviation of the septum to be usually to the left in right-handed persons, and vica versa, and thought that the deformity was due to the use of the handkerchief.

In conclusion, Dr. Delavan said he had intended to convey the impression that the hypertrophy of the turbinated bones consisted in a bladder-like expansion of portions of the bone. He also said it was not certain at what time of embryonic life the septum is formed, but that it was certain that it was soft some time after birth. The most important part is the treatment, and in all cases the operation for deviation of the septum is necessary.

Dr. Bosworth then opened the discussion on ozæna, its pathology and treatment, and stated that ozæna was always due to atrophic changes in the nasal mucous membrane, and that the treatment should be mildly stimulant. There were but few cases of cured ozæna, but many cases could be made comfortable and the odor held in abeyance by cleanliness.

Dr. Robinson, in discussion, said that many cases of the disease were caused by catarrh following the eruptive fevers, such as measles, scarlet fever, etc. The fetid odor does not entirely disappear after thorough cleansing, and he believed that perverted secretion was the cause of the odor.

Dr. Johnston, of Baltimore, said he had seen a case of perverted secretion giving rise to fetid odor and due to disease of the parietal sinuses.

Dr. Roe said he had found thorough cleansing of the nasal cavities and insufflation of boracic acid to be the most successful mode of treatment.

Dr. Johnston thought that nasal catarrh and ozæna were different diseases.

Dr. Jarvis then read a report of a case of disease of the antrum simulating ozæna.

I think the subject of antral catarrh, as a secondary manifestation to chronic nasal catarrh, merits careful consideration. It would have probably received more attention if it had occurred as frequently as complications of the antrum in atrophic ozæna, and as catarrh of the antrum due to deep-seated tooth fillings and the presence of foreign substances in this cavity. An interesting case of this kind came under my observation last month. The patient, a lady, had been racked with almost continuous pain, extending over three weeks in duration. She had suffered with hypertrophic nasal catarrh for many years. The pain was unilateral, being largely limited to the right side of the face;

* Nasal Polypi, etc., *Archives*, Vol. III, No. 2.

it coursed through the cheek, and by reason of the involvement of the anterior and posterior dental nerves, there was much odontalgia. The patient, almost crazed at times by intense suffering, had become dependent upon powerful narcotics to obtain relief. By gradual increase the doses of these drugs have become alarmingly large. Hearing was imperfect on the right side, and there was much conjunctival congestion. In spite of the expostulations of her dentist, she had one of the right upper bicuspids, removed.

The patient consulted the New York ophthalmologist, Dr. Mullendorf, who referred her to me, for a tumor of the nostril.

A large, inferior turbinated hypertrophy completely occluded the right nostril. I pierced it with my transfixion needle, and removed it with the ecraseur. A stream of fetid pus poured from the nostril on the withdrawal of the excised tissue.

With the assistance of Dr. Henry, I carefully treated the antrum, obtaining immediate relief, and in three weeks a permanent cure.

I believe the antral disease was, in this instance, brought about by the pressure of the hypertrophied tissues disorganizing the valve of the antrum, thus permiting the acrid catarrhal discharges to enter this cavity, but preventing their exit.

Dr. Langmaid said he had seen cases in which other secretions also had been perverted, and had given rise to a fetid odor.

Dr. Rumbold, of St. Louis, showed a nasal douche, for the thorough cleansing of the nasal cavities in these cases.

Dr. Ingals thought insoluble powders should not be thrown into the nasal cavities, as they gave rise to irritation, and that solutions were better than powders.

Dr. Hartman made mention of Gottstein's method of treating ozæna with cotton tampons, and stated that he had found no advantage in this method over others.

Dr. Seiler concurred with Dr. Hartman.

Dr. Bosworth, in closing the discussion, reiterated his statement, that if the nasal cavities were thoroughly cleansed no odor would remain, but that in many cases it was difficult to reach all portions of the nasal cavities with the cleansing solution. The odor was due to decomposed animal matter retained in the nose. Rhinitis hypertrophica and rhinitis atrophica cover all cases of catarrh, and include ozæna. The proper treatment for the latter disease is stimulating applications to the mucous membrane, and that the cotton tampon acted as a stimulant, therefore it did good, but it had the objection of being inconvenient to the patient.

Second Day.

Tuesday's session opened with a business meeting, in which, among others, the report of the Committee on Nomenclature was conditionally accepted.

After the business meeting Dr. Ingalls read a paper on Deflection of Septum, in which he said that deflection of the septum narium may be of traumatic origin or spontaneous; the latter most common. The cartilage and bony septum are both bent in many cases, the latter being apparently the mechanical result of firm articulation with the cartilage, in which the flexion usually commences. The flexion in cases of spontaneous origin apparently results from hyperplasia of the cartilage, the growth taking place mainly at the edges, as a result of which growth the cartilage is enlarged, and because of its position (being set as it were in an unyielding frame) the cartilage is forced to bend.

Causes traumatic or spontaneous; the latter can result from hyperæmia of the parts—chronic catarrh. Patients apply for relief because of obstructed respiration or bending of the nose. Usually find also excessive secretion from nasal mucous membrane and alteration of voice. As a rule, crooked noses are caused by flexion of the septum, which pushes the point of the nose toward the side of the concavity. For convenience of description they are divided into four classes:—

1st. Those in which there is simple bending of septum with a uniform concavity on one side and a corresponding convexity on the other.

2d. Those caused by direct injury, in which there is more or less bending of septum, with depression of nose, depending for the extent of the deformity on severity of injury, etc.

3d. Those in which flexion occurs only in cartilage, near nostril. This flexion may be so great as to occlude nostril by a nearly horizontal plate of the bent cartilage. These cases usually associated with considerable deformity of nose, due to crowding of its point to one side.

4th. Those in which flexion causes a longitudinal ridge running along the course of the articulation of vomer and cartilage.

In cases of spontaneous origin the process continues for an uncertain time, though probably in most cases at least two years.

Several operations have been recommended, the most prominent of which are those of Chassaignac, William Adams, and Goodwillie, but these have been more or less modified to suit individual cases.

In the first class of cases often no operation is needed, though Adam's operation would probably correct the deformity.

In the second class Adam's operation, or Steel's modification of it, is most suitable.

In the third and fourth classes no operation seems likely to be permanently successful which does not include removal of the redundant tissue.

Simple perforation is not to be recommended, because it will not cure the catarrh or remedy the deformity; besides, it favors the formation of scabs, etc.

For these cases the operation preferred consists of separating the mucous membrane, removing the redundant tissue, replacing the membrane, and then holding the septum in position until firm union has taken place. Anæsthetic to be used. Posterior nares of the closed side to be plugged before operation is begun. Just enough of septum to be removed, so that when returned to its normal position, the cut edges will be in apposition. The cartilage must be kept in position for some time by plugs in nostril. The result will be correction of deformity of nose, removal of nasal obstruction and its accompanying symptoms,

obstructed respiration, catarrh, and change of voice.

Then Dr. Jarvis read a paper on "A New Operation for the Deviation of the Nasal Septum," in which he advocated the removal of the projecting portions of the septum, by means of his wire snare, and claimed as the advantages of this over other operations, the bloodlessness and exemption from pain.

And Dr. Shurley read a report of two cases of lupoid ulceration of the septum, pointing out the difficulty of making a differential diagnosis be tween the ulcerations of lupus and those of syphilis.

These three papers were discussed together, and the discussion was virtually a reiteration of the opinions expressed in the discussion on Dr. Delavan's paper in regard to the causation of deviation of the septum.

Dr. Shurley, however, in closing the discussion, called attention to the value of iodoform as a local application in lupoid and syphilitic ulcerations.

AFTERNOON SESSION.

The session was opened by the reading of a paper on "Impaired Cardiac Power as an Efficient Cause of Congestive Affections of the Throat," by Dr. Beverly Robinson, of New York, in which the author called attention to the frequent occurrence of congestion of the upper air passages, due to loss of power in the heart, muscles, and to venous congestion, and that the proper treatment of such cases was the exhibition of heart tonics, combined with local astringent applications to the larynx and pharynx.

Dr. Shurley said, in the discussion following the reading of the paper, that he had met with cases in which the congestion of the larynx had been due to impaired power of the heart, and had found that local applications alone were of no avail in the treatment, but that they had at once improved under chloride of iron, with tincture of digitalis. He then said the ultimate causes of disease of the throat were too often overlooked by specialists, and the local symptoms treated heroically, when some other more central organ was the cause, without giving relief to the patient.

Dr. Seiler fully endorsed Dr. Shurley's remarks, and related a case in illustration. A young girl, presenting herself for treatment of some throat affection, he found, on examination, a general relaxation of the mucous membrane, and asking a few pointed questions, arrived at the conclusion that uterine disease was the cause of her throat trouble. He then advised the patient to tell her family physician about her uterine symptoms, and place herself under treatment for them, as local treatment of the throat would be of no avail in her case. The patient answered by saying, "Doctor, if I had known that you could see all the way down, I would not have come to you."

Dr. Daly also endorsed Dr. Robinson's views, and called attention to the frequent occurrence of pharyngeal disease due to gastric irritation.

A paper by Dr. Harrison Allen, on Pharyngeal Irritation, was then read by the secretary, which was chiefly a dissertation on the anatomical structure of the pharynx and soft palate. Dr. Allen advanced the theory that swelling of the pharyngeal tonsil and the presence of nasal polypi caused spasmodic contraction of the muscles of the soft palate, thus making rhinoscopic examination difficult, if not impossible.

Dr. Bosworth said that in his experience the presence of polypi in the nares did not interfere with rhinoscopic examination.

Dr. Ingals said he was in the habit of making the rhinoscopic examination first, as he had found that after irritation of the pharynx had been produced by the laryngeal mirror it was much more difficult to obtain a view of the parts.

Dr. Daly said that telling the patient to breathe through his nose while the mirror is in situ, caused the soft palate to drop and facilitated rhinoscopy.

Dr. Knight then exhibited a case of "Aphonia Spastica," or laryngeal stammering, which was examined by the members present. After the patient had retired he said that the disease was a rare one, and that he had not seen a case until after the paper of Schnitzler had been published. It was progressive, and considered incurable, and was produced by a spasm of the tensor muscles of the vocal cords and of the respiratory muscles. He was treating the patient by galvanism and gave him nerve tonics.

Dr. Longmaid said he had a similar case under observation, in which, lately, symptoms of degeneration of the spinal cord had appeared.

Dr. Elsberg said he would advise vocal gymnastics in addition to the galvanism and nerve tonics, and thought the prognosis was not hopeless in those cases which did not depend upon central nerve lesions.

Dr. Daly then read a paper on Catarrh Involving the Antrum, and its treatment, which was a report of two cases of antral disease with extremely fetid discharge which were cured by removing a tooth, opening the antrum and treating its lining mucous membrane with astringent injections.

Dr. Shurley said he had seen two cases of antral disease, but without offensive discha ge, and had treated them by opening the antrum and by injecting a strong solution of chlorate potassium.

Dr. Seiler then opened the discussion on Laryngeal Ulcers, and said that there were several kinds of ulcerations of the mucous membrane of the larynx. First, abrasions, which amounted to mere lacerated loss of epithelium, and were not covered by pus, occurring mostly in those parts which were subjected to friction, such as the edge of the epiglottis and the interarytenoid space. Second, shallow ulcerations, involving the whole depth of the mucous membrane, and covered with creamy secretion, resembling pus. The so-called catarrhal ulcerations, also chiefly found in the parts most exposed to friction, and third, the deep destructive ulcerations, which affect and destroy the tissues below the mucous membrane. The latter are always due to some specific poison in the system, such as syphilis, or tuberculosis, and are invariably the result of the breaking down of gummata in syphilis, and cheesy deposits in phthisis. The syphilitic ulcerations had the peculiarity of being symmetrical on both sides, and that the shallow catarrhal ulcer

was also observed in this disease, as well as in ordinary catarrhal inflammation.

Dr. Bosworth said he did not believe in the so-called catarrhal ulcer without a specific cause, and that the shallow ulcer of syphilis was due to ulceration of mucous patches. If there was no catarrhal ulcer then no ulcer existed in the larynx that was not due to specific cause.

Dr. Jarvis said that he also did not believe in the existence of a catarrhal ulceration, but that he had met with ulcerations of the mucous membrane, not due to either phthisis, or syphilis, or cancer—especially in the mouth.

Dr. Robinson said he had seen in catarrhal laryngitis, lenticular abrasions in the laryngeal mucous membrane, which might be called catarrhal ulcers, which resembled closely the abrasions seen in herpetic pharyngitis, and that probably the so-called catarrhal ulcer was nothing but a herpetic sore.

Third Day's Session.

The session was opened by the reading of a paper by Dr. Wagner, on "A Case of Expulsion of the Ossified Arytenoid Cartilage following Thyrotomy." The author not being present, the paper was read by the Secretary. In the paper, the author related the history of a case of papilloma of the larynx, which for its removal necessitated the operation of thyrotomy. The thyroid cartilage was found to be ossified, and had to be cut with a saw. Three weeks after the operation the patient was discharged as cured, but returned to the hospital three weeks later bringing with him a piece of bone which had been expelled during a fit of coughing. This, on examination, proved to be the ossified left arytenoid cartilage.

Dr. Seiler said that he had seen two cases of loss of arytenoid cartilage, in one of which the cartilage had been expelled during a fit of coughing. In both cases the perichondritis had been due to syphilis.

Dr. Longmaid then opened the discussion on the "Physiology, Pathology and Treatment of the Singing Voice." He said the subject was too extended to be discussed within the limited time at the disposal of the Association, but that he had a few points he would bring before the meeting. First, the effect of slight catarrhal inflammation of the cords upon the voice. He had observed that under such conditions the voice of singers was passable up to a certain point, but that beyond this the voice gave out entirely. The removal of the inflammation restored the voice. Second, the influence of the nasal cavity upon the voice; and thirdly, does excision of the tonsils injure the voice or not. He thought that excision of hypertrophied tonsils did not injure the voice, but improved it. He then showed a case of hypertrophied adenoid tissue of the vault of the pharynx, in which the quality of the voice was much altered.

Dr. Jarvis said that the alteration of the voice caused by nasal disease was very readily demonstrated, and that frequently chronic inflammation of the vocal cords was due to nasal catarrh.

Dr. Seiler said that, in a paper read at the last meeting of the Association, he had proved that the nasal cavities exerted a very great influence upon the voice, and stenosis, or even narrowing of the nostrils, would produce an alteration of the voice.

Dr. Roe said he concurred with Dr. Jarvis and Dr. Seiler, that the nasal cavities greatly affected the voice, and called attention to the evil results of overstraining of the voice, after a prolonged rest, in singers.

Dr. Ingals deplored the want of unanimity of opinion in regard to the effect of nasal disease upon the voice, and said he was of the opinion that unless the voice was greatly altered, an operation within the nose was uncalled for.

Dr. Jarvis took exception to this statement, and said that if there existed any encroachment upon the normal calibre of the nasal cavities, it should be removed. If it did not alter the voice then, it would certainly do so in the near future.

Dr. Deblais related a case of a male soprano, who, through nasal disease, was prevented from singing in public, and after the cure of his catarrh was again able to sing.

All the members were unanimous in the opinion that tonsillotomy does not interfere with the voice.

Dr. Morgan said that the concerted singing of children in public schools was very injurious to the voice, and that, in his experience, many cases of chronic throat disease had their origin in this pernicious practice.

Dr. Roe then opened the discussion on the utility of topical applications in chronic laryngitis, calling attention to the indiscriminate use of the brush or probang by the general practitioners, in the treatment of throat diseases.

In the discussion which followed the members were unanimous in the opinion that local and general treatment should be combined. The meeting then went into executive session, and elected the following officers for the ensuing year: President, Dr. G. M. Lefferts, New York; First Vice President, Dr. Carl Seiler, Philadelphia; Second Vice President, Dr. F. Ingals, Chicago; Secretary and Treasurer, Dr. D. B. Delavan, New York; and decided to meet next year in New York City.

Medical Banquet at Little Rock.

On Tuesday, June 1st, the physicians of Little Rock tendered a complimentary banquet to the Arkansas State Medical Society, in session at Little Rock. The bill-of-fare was handsomely printed on an amputating saw, made of cardboard. The following toasts were proposed and responded to:—

1. "The State Medical Society of Arkansas"—A. N. Carrigan, M.D.
2. "Our Retiring President"—R. G. Jennings, M.D.
3. "Our President Elect."
4. "Saddle Bags."—W. H. Hawkins, M.D.
5. "The Music in Medicine"—T. E. Murrell, M.D.
6. "Our Medical Colleges"—Wm. Thompson, M.D.
7. "Our Bachelor Brethren"—J. H. Lenow, M.D.
8. "Ye Jolly Doctor"—J. M. Keller, M.D.

Card from Prof. John J. Reese.

To the Editor of the Medical and Surgical Reporter:—

Dear Sir: I beg to avail myself of your courtesy, to correct an error in connection with the report in last week's daily papers of an autopsy made by myself and Dr. Cadwalader, acting Coroner's Physician, of a woman supposed to have been drowned in the river Delaware.

The reporters of the case, in their desire to make it as graphic as possible, have put *their own* interpretation upon the results of this autopsy, while making it appear to the reader that they are expressing *my* views; and inasmuch as these inferences do not seem to me to be fully warranted from a single isolated case, especially where there was no absolute proof that the death was *caused* by drowning, I do not wish to be considered as endorsing the rather premature conclusions attributed to me by those well meaning but over zealous reporters.

Certainly, the leading authorities all teach that the presence of water in the lungs and stomach (especially the former) constitutes the most reliable evidence of death from drowning. And the entire absence of water from both the lungs and stomach, in the autopsy referred to, was undoubtedly a very noticeable feature, *provided* we were certain that drowning was the real cause of death, which we were not, as the case was one of a multitude of similar ones on which the Coroner's jury pronounces the usual stereotyped verdict of "found drowned."

It is evidently a very important point for the legal physician to settle: What are the positive, unequivocal signs of death by drowning? It may, in truth, become the *vital* point to establish in a capital case, as would appear to be the fact in the now pending Malley case. But in order to establish an important scientific truth, the experiments should be repeated, under varied circumstances, until every doubt is removed.

I may be permitted to say, in this connection, that I am now engaged in investigating the post-mortem appearances in cases of death from drowning, as a legitimate object of inquiry connected with medical jurisprudence; but I had not the remotest idea that the results of the late autopsy, which was conducted with the strictest privacy, and which was only part of a series of observations of a similar nature, would have fallen under the ken of the ubiquitous "reporter," and been made to assume a coloring not designed by myself.

John J. Reese, M,D.

316 *South Twenty-first St., June 26th*, 1882.

The Berlin Hygienic Exhibition.

Careful investigation of the ruined Hygienic Exhibition has resulted in the unfortunate conclusion that nearly a year must elapse before the buildings and collections can be sufficiently restored to open the exhibition. It would seem that the preparations to meet emergencies, particularly the supply of water in case of fire, were totally inadequate, and also that, to save money, the directors had purchased the well-dried materials from the committee of least year's Industrial Exhibition in Halle.

Items.

—Drs. Fordyce Barker, Austin Flint and John G. Adams, have been appointed delegates from the New York Academy of Medicine to the International Congress of Hygiene, which meets in Geneva, Switzerland, from the 4th to the 9th of September.

—It is announced that the French Minister of Marine has placed at the disposition of M. Alphonse Milne-Edwards the vessel, Le Travailleur, for a dredging expedition in the Bay o Biscay, as far as the Canary Islands. The operations, which are to be made with a view to studying the fauna and flora in deep sea, will take place during July and August.

The Sweating Sickness of the 16th Century.

The Boston *Medical and Surgical Journal* contains an interesting account of this strange disease that visited England five times in the early part of the 16th century, and carried off over thirty thousand victims. The disease usually began with a little fever, possibly a slight pain in the head and heart; when suddenly a most profuse sweating would occur, by which such great prostration was produced that in many cases the victims died in two or three hours. It would seem that the disease was due to defective hygienic surroundings and to improper modes of life. Drugs had little or no influence over it. The disease was not always fatal, nor did one attack protect from a second. Cardinal Wolsey was four times attacked. The disease has now disappeared from England, but it was observed among the Turks during the Crimean war, in the hospitals at Scutari.

QUERIES AND REPLIES.

T. C., of Pa., is answered as follows: When the twins are male and female, the latter is called "Free Martin;" when full grown resembles a steer, and does not conceive; highly esteemed in England for beef cattle.

MARRIAGES.

CLOW—SARVER.—On Thursday, June 1st, 1882, at the residence of the bride's parents, 210 Locust street, Allegheny, Pa., by Rev. J. W. Witherspoon, assisted by Rev. J. Sarver, of Luchburg, Pa., Miss Maggie A. Sarver, daughter of William Sarver, M.D., and Mr. Will. E. Clow, of Chicago, Ill.

PECK—WILLIAMS.—At West Livingston, N. J., Wednesday evening, May 17, 1882, by the Rev. J. A. Ferguson, E. E. Peck, M.D., of Caldwell, N. J, and Nellie L'Hommedieu, only daughter of J. C. and Agnes J. Williams.

REYNOLDS—SMITH.—In this city, May 29, ult. at the residence of the bride, No. 1324 Hanover street, by Rev. Dr. M. T. Eva, A. Sidney Reynolds, M.D., and Miss Lizzie Smith, all of this city.

SEAMAN—TOWNSEND.—At St. Paul's Episcopal Church, Glen Cove, Long Island, June 8, 1882, by the Rev. Dr. John C. Middleton, Richard F. B. Seaman, M.D., and Sadie L., daughter of Mary Embrie and the late Frederic E. Townsend.

WENTZ—ULP.—On Thursday, June 1, 1882, at St. Barnabas P. E. Church, Haddington, West Philadelphia, by the Rev. John G. Bawn, Alexander C. Wentz, M.D., of Hanover, Pa., and Miss Clara B. Ulp, of West Philadelphia.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

THE ELECTRICAL BATH.

A Paper read before the Albany (N. Y.) County Medical Society,

BY W. O. STILLMAN, A.M., M.D.,
Of Saratoga Springs, N. Y.

The administration of electricity through water is almost synchronous with the discovery of that agent, and the use of water has ever since almost always accompanied its application in one way or another. Its use through the medium of the thermal bath, in the manner which I am about to describe, is, I think, a recent innovation, and one which I am sincerely convinced possesses very great remedial virtues, and which is destined to occupy a high position in the esteem of the profession.

This is said after a four years' experience in its almost constant employment in a great variety of diseases, principally chronic, and I think it fully deserves to rank, in its special line of application, with the Turkish and Russian baths in their special lines, as of equal if not superior merit; while as a simple tonic measure I know of nothing that equals it.

In looking over the standard writers on the subject of electricity very little mention is made of its use in the bath. Gerratt, Althaus, Beard and Rockwell, and others, mention the electro-chemical bath, by means of which it is alleged that various mineral substances, such as lead, mercury, silver, etc., have been extracted from the human body. As I have had no experience with this process, first presented to the profession in 1855 by M. Poey, through a paper read before the French Academy, and as its claims are, I believe, without scientific support, I have nothing to say concerning it.

There is little or no mention made of electricity, administered by means of a bath, in any of the standard works upon materia medica or therapeutics, and it is only in such writers as Tibbits, Beard, and Rockwell and Schweig that even a passing reference occurs. The latter, indeed, enthusiastically urges its merits at length, but the first two concede the possibility of its value in a reluctant manner and with but crude explanations of its thorough and rational application.

In using the term "electro-thermal bath," I employ it in a very restricted sense. It is intended to refer only to the use of the *faradic* current in the warm or hot bath, applied principally through the medium of the water, and on the principle of general faradization, which has attracted so much attention of late among well recognized specialists, from its satisfactory results. The galvanic current, which I have also used in the bath, has not been found so useful as when applied locally outside the tub. As I have used both the faradic and galvanic currents, both in and out of the bath, and side by side, for several years, and have seen their effects in at least five thousand applications, I may at least claim to have studied various sides of the subject, and to be not especially prejudiced in favor of the method of which I am speaking. Indeed, I have made more use of the galvanic current out of than of the faradic in the water.

As I am *not* an electric specialist, I hope to speak without a specialist's unintentional bias or

prejudice. Neither do I wish to be understood as regarding electricity in the least—in any of its forms of application—as a cure-all or panacea. In speaking of my special topic I only urge it as an improved method of administering this valuable agent in certain cases and for certain maladies.

A brief description of the bath and its appliances is necessary for a correct understanding of its therapeutical uses. Its requisites are very few and simple. A battery, connections, electrodes, a tub and water, are all that is needed. Any non-conducting material, such as wood, porcelain, soapstone, vulcanized rubber or glass, may be used for the tub. It may be of the ordinary size and shape, but is preferably somewhat deeper and without the inclined plane at the head, which would interfere with the movement of the electrodes. A metal rod is placed in a deep groove running the entire length of the tub on either side, and within a couple of inches of the top. To each of these rods is appended a single electrode, which may be slid along on the rod from one end of the tub to the other, its connection with the battery being constantly maintained by means of the rod. Both rods are connected with the battery, one with the negative the other with the positive pole, but so arranged that by the aid of a commutator the current and the poles may be reversed at pleasure.

The electrodes may be either of carbon or metal, and should extend at least eight or ten inches below the surface of the water. In addition to these a single ordinary movable electrode is provided, which may be applied to the person at special points, as desired. This should then represent one pole and the tub electrodes the other. All that remains is to provide any good induction battery of large quantity, and connect it with the tub as described.

The administration of the bath is as simple as the apparatus. It may be passed in descending current from one shoulder to the opposite foot, then from the opposite shoulder to the other foot. It may be passed through the liver, as a stimulus to that organ, through the bowels, for constipation, assisted in both instances by the movable electrode if desired, or the use of a rectal electrode in the latter case, in place of the sponge. It may be passed through the hips and thighs, for sciatica, or the legs or arms, for atrophied muscles, paralysis, rheumatism, gout, etc., or applied locally, for neuralgic pains, anæsthesia, disturbances of sensation, etc., at almost any point on the person. For general tonic purposes excellent effects are obtained by passing the movable electrode over the spine, the two attached to the tub being placed by the feet and the current being so adjusted that they represent the negative and the movable electrode the positive poles of the battery, respectively.

The various special applications, or modifications of those suggested, are, of course, endless, and would readily suggest themselves to the operator as indicated by the individual needs of each case. The duration of the bath is usually about fifteen minutes, but may vary five minutes either way, and in some cases has to be limited to a still shorter time. The strength of the current has to be determined, as in most cases, by the sensibility of the patient, and the length of the vibrations by the judgment of the electrician.

Concerning the merits or superior advantages of this method of applying the faradic current considerable may be said.

It has been my experience, in using it in this manner in a large number of cases, that it has unquestionable advantages, in certain lines of maladies, over either the galvanic or faradic currents out of the water, and both methods have, as I have said, been used side by side. There have been seen very marked and satisfactory recoveries or improvements resulting from its employment, more, in my judgment, than could have occurred by the older plan of administration.

A number of years ago Drs. Beard and Rockwell called the attention of the profession to the use of what they called "general faradization," and insisted so strongly upon its merits that it was freely tried on both sides of the Atlantic. Many leading physicians endorsed its use, and prescribed it with excellent effects. "General faradization," according to them, consisted in simply faradizing the system generally, in detail; the use of the hand as an electrode being strongly advised. There can be no doubt that most excellent results have been obtained in this manner, but that the bath, more thoroughly and effectually, more agreeably and generally, and that with less fatigue and inconvenience to both patient and operator, accomplishes the same ends, seems to my mind a matter of no doubt. If the object of general faradization is to reach all parts of the body uniformly and completely, the bath accomplishes that object more effectually than any other plan. If it be to produce localized effects on any portion of the body, that also can be as efficiently and more gently accomplished. If the use of the hand as an electrode be urged, the water offers an agent as adaptive, as soothing, and more conductive, and which, at the same time, greatly increases the conductivity of the parts.

A not unimportant factor in administering electricity is the resistance offered by the skin. It is often like sending the current through a deal board, so dry, and hard, and cold, and consequently non-conductive, is it. Poore, the English electrician, calculates that the resistance offered by the body to the passage of electricity is four times greater than that of an Atlantic cable. Hot or warm water overcomes this as effectually as any means, and when applied in considerable quantity, as in the bath, the afflux of blood to the skin vastly increases its conductive power in addition to simply moistening the exterior. The person is also protected from atmospheric exposure by the even temperature of the bath, and from the cold consequent upon the evaporation of the warm water ordinarily used on the sponges of the electrodes. The liability to a cold after a warm bath is generally considered by electricians, I believe, to be greatly diminished by the use of the electricity. In my experience it almost never occurs.

The advantages claimed for this method may be briefly reviewed as follows: Where the bath is used as a general tonic, or for the relief of a disease affecting large portions of the body, as paralysis, rheumatism, etc., the electricity can be applied more thoroughly and gently, agreeably if you choose, and with better results, than by the usual plan. Its application to the surface is equalized; the skin is in better condition to conduct the current; it is less fatiguing to the patient; the vaso-motor system and nutrition and innervation are more profoundly affected; and some of the uncomfortable features of general faradization are obviated.

If it is desired to secure localized effects, they can be attained by means of the movable electrode, or often by the position of those attached to the tub. Local and diffused effects can in this way be secured at the same time, if desired. Where *strictly* local treatment is indicated, as in aphonia, neuralgia affecting a single extremity, writers' cramp, bronchocele, etc., I do not claim a special advantage for this method over the one ordinarily employed, and it certainly involves unnecessary labor in dressing, drying, etc. The additional inconveniences, however, attending the bath, over "general faradization," are practically insufficient to require consideration.

One or two practical points, and I will only detain your attention long enough to give a resumé of the diseases in which I have seen its use attended with the most beneficial results. A surgeon to the Massachusetts General Hospital once told me, "why you can get little or no electricity in the water in that way, without touching the electrodes. All I can say is "try it." I have seen a strong man doubled up as though he had been struck in the epigastrium by a club, in determining that point. From strong spasmodic muscular contractions the current can easily be so graduated as to be felt only as though a gentle breeze were blowing on the skin.

In regard to age or constitution, I have seen it used with equally good effect by children and old people, delicate and robust. The temperature of the water usually ranges between 90 and 100° Fah., the average being 95°. The baths may be given from one to three times weekly. It has been my experience that little or no better effects result from using them any oftener. They should not be used too soon after meals. It may be necessary to continue them a number of weeks before improvement shows itself, although, as a rule, this is not the case, amelioration of symptoms and manifestations of the disease usually occurring early, if any benefit is to be derived. In a very small percentage of cases these baths cannot be taken. These exceptions usually occur in those who cannot take the faradic current in any form of administration, or who cannot take a warm bath. With these the galvanic often answers admirably. I have not observed that some temperaments will bear electricity in the bath which will not tolerate it elsewhere, as has been stated by some observers.

The field of diseases to which this bath is applicable is quite wide, and embraces many of those which are most commonly met with. It is not by any means confined to diseases of the nervous system. Rheumatism, gout, dyspepsia, general debility, constipation, malaria, sluggish liver, nutrition and circulation, benign tumors, simple muscular atrophy, amenorrhœa, impotence, sprains, synovitis after the acute stage, opium habit, alcoholism, etc., are among the most prominent of those met with in which its exhibition is attended with marked beneficial results.

In rheumatism, whether in the acute, sub-acute or chronic stages, its effects are often almost magical, the therapeutical effect of the hot water being superadded to those of the electricity, besides being efficacious. It is certainly a most agreeable way of applying this agent in this malady. The same holds true in regard to gout, which is not, however, so uniformly cured.

In general debility I know of no single remedial agent which produces such excellent results. A person, before taking the electricity, may be oppressed by a feeling of lassitude and weari-

ness, but will come out of the bath doubling up the biceps, to show his spirits, and with a delightful feeling of buoyancy and invigoration. The circulation is quickened, and the cutaneous capillaries learn the lost art of dilating again. The appetite is often markedly improved, tissue metamorphosis is hastened, the liver and bowels are stimulated, the general functions of nutrition assume a new activity.

In constipation and dyspepsia, its use is often attended with great improvement or recovery, but not more so than with many other means. In malaria it seems to be a very useful eliminator and tonic, fortifying the body against the inroads of the subtle poison. In torpidity of the liver it offers a direct stimulant, potent and efficient. In simple muscular atrophy it is almost the remedy *par excellence*, and does a great deal toward restoring lost functions and strength.

In benignant tumors of various descriptions it has not proved nearly so reliable as the galvanic current, in my experience, although often valuable, alternated with that current. For amenorrhœa, with the vaginal electrode, it offers one of the most powerful agents with which I am acquainted; indeed, it will often bring the menses on before their time—an accident to be guarded against. It is also quite useful in impotence. In both sprains and synovitis, I have seen marked improvement under its use, but not, I must confess, very rapid, although more so, I think, than with simple medicinal treatment alone. In opium habit and chronic alcoholism, it usually completely subdues the inordinate appetite while in the bath, and its effects usually continue in lessening degree for several hours afterward. It recommends itself as a valuable aid to the means usually employed in the treatment of these affections. I have not observed the hypnotic effect from the faradic current, to any extent, which some writers have dwelt upon, and which is so marked a characteristic of the galvanic current.

In nervous disorders the range of the application of the electro-thermal bath is also large. I have observed beneficial effects in local anæsthesia, in nearly all the pareses, whether from central or peripheral lesions, or from lead, arsenical or malarial poisoning. An interesting case of arsenical paralysis of the legs below the knees is now under treatment. In neurasthenia with its myriad attendant symptoms, in disturbance of sensation, in hysteria, in its numerous manifestations, in melancholia, and in almost all forms of neuralgia, it offers a useful and often speedily curative remedy. The list might be much lengthened, but the number presented will suffice as an illustration of its field of usefulness, and are presented from cases actually treated.

In many nervous diseases I greatly prefer the galvanic current, from its much greater sedative effects. Thus, in locomotor ataxia, epilepsy, insomnia, cephalalgia, chorea, herpes, most inflammatory conditions, tinnitus aurium, hyperæsthesia, etc., it has seemed to me most advantageously employed.

In closing, I would remark that the electrical baths which I have seen figured or described in books have seemed "exceedingly crude," as Beard and Rockwell have denominated them. This, however, is not a proper time or place to discuss them differentially. The few facts which I have presented from my experience, in so rough an outline, I have tried to give in the interests of medical progress, not unmindful of the fact that there exists a prejudice in the minds of many against both electricity and everything balneological.

PNEUMONIA TREATED BY VENESECTION.

BY JOSEPH STUBBS, M.D.,
Of London Grove, Pa.

Perhaps no one who claims to be read up in the periodical literature of the day has failed to read the interesting articles of Dr. Hiram Corson, on "Blood-letting in Acute Inflammatory Diseases; more Especially in Pneumonia."—MEDICAL AND SURGICAL REPORTER, Vol. 44, Nos. 3, 7, 10, and 16, and Vol. 46, No. 14. The strong testimony and practical bearing of those papers, coming from a man of long experience and close observation, elicited a deep interest in the profession. The same views were ably sustained by Professor S. D. Gross, and Dr. E. Michener, who added the weight of their extended experience in favor of reviewing the "lost art" of blood-letting in inflammatory diseases.—*Country Practitioner, Feb., March, and April*, 1881.

Strongly impressed with the testimony of a trio of such men, drawn from their own personal observation and experience, in favor of bleeding as the first, indeed, as *the* remedy in pneumonia, I had resolved to test it for myself whenever an opportunity should present. I did not wait long, until Dr. Michener, one of the trio named, himself became my patient. I was called from my bed at an early hour on the morning of Second Month 26th, 1881, to visit him, and promptly responded to the call. He gave me the following history:—

"I am now in my eighty-seventh year. Five

days ago I fell on the ice and sustained a transverse fracture of the humerus, near its upper extremity. There was no displacement of the fragments, and it appeared to be doing well. There was no unusual shock or irritation. Last evening I was quite chilly, without any sensible cause, had tenderness and aching in the submaxillary glands, more marked in the tonsils. On retiring, after a short sleep, I awoke; the signs of the evening had passed away, and were replaced by others of a graver character. I now had well pronounced fever, accompanied with weight and a burning sensation in the right thorax. The breathing was oppressed and hurried, more so when lying down. These symptoms were persistently aggravated during the remainder of the night."

I found him with a dry, hot skin, the pulse frequent and feeble, or rather oppressed. There was dyspnœa, the breathing short and hurried, with oppression and some pain through the right mammary region, increased by coughing, lying down, or attempting to draw a full inspiration. The percussion sounds were not much changed. The respiratory sounds were feeble and harsh, with crepitant ronchus, quite distinct, over the right lung. My diagnosis was pneumonia, to which conclusion the Doctor had already arrived.

Although I had just read the Doctor's article in the *Practitioner*, in which he so strongly recommends blood-letting in this disease, I said to him: "Doctor, notwithstanding your views in reference to blood-letting, you would not advise it here, on account of your advanced age. You are too old to be bled." The prompt reply was: "That must be tried. I do not know that age should make any difference. If I have but a little blood in store, a proportionate quantity should afford relief, especially now, while the disease is still in the congestive stage. If thee does not wish to use the lancet, I shall be obliged to use it myself."

I, of course, assented. He then handed me his lancet, with explicit directions how to proceed.

"I prefer to sit up. A less quantity of blood will suffice. When the vein is opened, then apply the ear to the chest and the finger to the pulse, and carefully watch the results, without much attention to what may be in the bowl. Remember, that our purpose is to relieve the lung of its burden. As that is accomplished, the blood will again resume its course. The pulse will become slower, fuller and softer. The skin will lose its unnatural heat, perhaps become moist. The lung sounds will become normal, and I shall be able to draw a full inspiration. When these ends are reached, it will be time to stop the blood. Probably not until then."

The Doctor's programme was strictly observed and the changes distinctly noticed. When he drew the first free breath, the blood was immediately stopped. On recurring to the vessel, it was found to contain ℥ xv of blood.

It is needless to extend the report of this case further. Indeed, I had no case left to report. The disease was suddenly and completely aborted, and required no further attention. My only prescription, a mild expectorant, was never used. It is proper to add that the lung has not been left crippled, as too often happens under adverse modes of treatment. If bleeding will do this for a *spare man, of the Doctor's age*, what ought we to expect from its use in young and plethoric subjects? I am now convinced that the danger from blood-letting has been as much exaggerated as its use has been neglected. If so, it is not unreasonable to suppose that many valuable lives have been allowed to perish for the want of its timely and judicious employment.

Remarks by the Patient.—Even when blood-letting was in the ascendant, many physicians hesitated to use the lancet in the later periods of life, lest the recuperative powers should be too feeble to restore the waste of the vital fluid. While proper caution is always commendable, there is no proof that this hesitancy is well founded. It is obvious that the grade of morbid action, and the quantity of blood required to subdue it, are dependent on the same conditions. Many months have elapsed since the occurrence, and there is no sensible impairment of my physical or mental condition which can be attributed to the loss of blood on that occasion.

Whatever may be the opinion or the prejudice of the reader in relation to this case, it presents three striking features which can hardly be questioned:—

A rapid and extensive congestion of the lung.

A high grade of morbid action tending to destruction of important vital tissue, and

A sudden and complete arrest of the disease by blood-letting alone.

For all practical purposes pneumonia is an acute inflammation of the lung; nothing more, nothing less. It represents three stages: the congestive, the inflammatory and the destructive stage. Their peculiar organism and complex functions determine the character and the fatal tendency of the disease, and demand for it that prompt and immediate relief which the lancet is

so admirably adapted to afford, as shown in my case. We unhesitatingly place it on record as a *paragon* of therapeutic practice. It is not new. There have been many such cases, and there will be many more. Physicians will not always ignore the facts of their own experience. And the people will learn to prefer prompt and easy relief from the lancet, to the feeding, stimulating process which so often fails in the end.

REPORT OF TYPHOID CASES.

BY T. CURTIS SMITH, M.D.,
Of Aurora, Ind.

The following history of a bit of experience in a circumscribed endemic of typhoid fever may not be without interest, although it is in some measure a repetition of old statements, made and reiterated many times by many writers:—

On the 15th of Dec., 1881, I was called to see S. A., aged 14, one of a family composed of the father, three sisters and one brother. One sister was aged 17, one 12, one 6, and the brother 8. The father was a puddler in the iron mill of this city. The place of residence was a frame dwelling, with basement kitchen, and cellar, two rooms on the ground floor, and bed-rooms on the second floor. It was a neat double cottage, seemingly well arranged for tenant use at a moderate rental. Unfortunately, the basement story was so low that when there was any quite high swell in the Ohio river (as there is nearly every year, often several times in a year), the water rises over the floor, and drives the occupants to the story above. The water supply was derived from a cemented cistern near the basement kitchen door, the top of which was lower than the basement floor. The back-water would, therefore, sometimes enter and fill the cistern before rising enough to enter the basement of the dwelling. It is to this water supply in the cistern and the character of the back-water that we wish to call special attention. This city, Aurora, is situated on the north bank of the Ohio river, and is divided by Hogan creek into two parts. There is much low ground within the city limits, that is almost yearly overflowed by back-water. The residence in question was located on this low ground. We desire you to note that on the right bank of Hogan creek, about two hundred yards from this dwelling, is a large distillery, with accompanying hog and cattle pens, where many hundreds of these animals are fed every year. The debris from these pens runs down into the creek, and when the creek is low it accumulates in vast quantities, yielding no very roseate odor, but is, in fact, a nauseous insult to every man's olfactory that comes near it in hot weather. Besides the filth that runs into the creek, much accumulates under and about the pens. Over this the water rises at times and soaks away much of its power for mischief. Now, it so happens, from the lay of the banks of this creek, that the first place where the back-water breaks over its boundaries is quite opposite the residence in question, and about one hundred yards from where it is located. There is no perceptible current in the water when it backs toward this house, yet any one can at once see that water rising over this mass of filth can but be impure in a marked degree; and this is the kind of water that has more than once filled the cistern at the residence before named. Still further, there stands about forty feet from the cistern a double privy, which the back-water enters before reaching the cistern. Its contents, of course, go into the water, and certainly take nothing of purity and healthfulness away from the already muddy, filthy flood. This water, whether foul or not, finally rises above and pours into the mouth of the cistern, near the kitchen door. No one need be told of the heavy sediment always left by back-water, where it stands any considerable time. There must, therefore, also, of necessity, be a sediment left in the bottom of the cistern in question. It could not be otherwise. Now the landlord always has the water pumped out of the cistern after the back-water goes down. This is right. But he does not always have it scrubbed and well washed out, in order to remove all the filthy sediment that is, of course, left behind. This is the situation and environment, in a sanitary sense, in which I found the family in question. Whether the water was the cause of, or carried in solution, the germ that gave rise to typhoid fever I do not know, but I do know that I could find no other cause in the house or surroundings, nor in the diet of the family. I will further say that the house was kept neat and clean, so that nothing in the house could be laid to the charge of the housekeeper, in the way of want of cleanliness.

But while we have called special attention to the qualities of the back-water as destroying the healthful qualities of the drinking water in the cistern by overflowing its top, we wish also to say that, according to the best judgment we could form, the cistern also leaked and permitted this sweet flavored (?) surface water to flow into its already impure contents. A day or two after it had been pumped dry as the pump in it would permit, there was no trouble in again pumping

water out of it, though none had been permitted to run into it from the roof.

Another fact worthy of note, as a disease producing factor, is the fact that this same back-water left its unwholesome sediment all over the flat bottom land round about this and other dwellings adjacent to it. This same water also, rising over the basement floor and into the cellar, would have no wholesome effect to leave after its recession.

Moreover, a whole family living in the next house to the one in question, and somewhat similarly situated as to water supply, were twice poisoned by the water in their cistern. At least, this was the cause given the attending physician at the times of their illness. Five other families round about this habitation have not had typhoid fever nor malignant diseases, recently, as far as I know; but during the hot dry months of last summer and autumn I treated a number of cases of most obstinate diarrhœa in children, in the same neighborhood, and some in this same house. On the east side of this flat I treated also some most villainous attacks of dysentery, that refused to yield until the patients were removed to a more wholesome locality. And during the month of December, 1881, I treated in the same house, last above named, two cases of diarrhœa, with malarial complications, on which I could make little impression while living in that place. On removal, the disease disappeared in a little time. In this instance also a surface water cistern—for it was practically such—seemed to be the source of the diseases afflicting the inmates.

Returning now to the family first named, the boy, aged 14, was attacked with a violent cold, and reported to me on December 15th, 1881. There was considerable pulmonary congestion, high temperature, and well marked cerebral disturbance, within the next forty-eight hours. These measurably subsided, so that he seemed quite relieved, but still had a white, tremulous tongue, high pulse and temperature. By the fourth day from first reporting to me at my office there could be no doubt that we had to deal with a severe attack of typhoid, with some pulmonary disease still remaining, and cerebral symptoms for a time uppermost. But the whole trouble settled into a regular but fierce attack of pure typhoid, which, but for the greatest care, must quite surely have ended fatally. On the 26th of December, thirteen days after the first case was attacked, the oldest daughter, aged 18, began to manifest prodromic symptoms of the same form of fever, and January 1st, 1882, took to her bed, where she remained for four weeks, the fever leaving her on the eighteenth day, prostrate, anæmic, thin and weak. The fever in the lad before named continued to the twenty-first day, when it subsided.

On Jan. 10th, 1882, the youngest boy, aged 8, manifested clearly the presence of the fever, though he played as usual, or went on short errands and chores for the family. Still, for two weeks, I did not find his temperature below 101° in the morning and 103° in the evening, and for four days it ran up to 103° in the morning and 105° in the evening. He became very thin and pale, had some diarrhœa, pulse rapid and feeble, but he all the time had a good appetite, digested his food well, slept well, and never took to his bed. Often complained of being tired. This was as clear a case of "walking typhoid" as I have ever seen, and without the thermometer might have escaped without a correct diagnosis until brought down. He was treated as regularly as those who were prostrated and in bed, only less restricted in his movements and diet.

On the 8th of Jan., the second daughter, aged 12, began to complain and show quite a rise in temperature. On the 10th, took to her bed, to endure a more prolonged stretch of high temperature than either of the preceding cases. The onset of the second week gave a temperature of 103 in the morning and 105 in the evening. This soon changed to 104° morning, 105° evening, and, with the exception of a slight morning variation, and once running up to 105½° evening, it stood at this for ten days, without a break in its even range, then dropped to 102° and 101° morning, and 104°, 103, then 105° evening. For days life trembled as in the balance, before any break in temperature came that offered a ray of hope. The first case mentioned was also a most fierce attack. The general range of temperature averaged throughout was not much above that of the average cases of typhoid, but at one time the thermometer registered 106.5°, several times 105°, often 104°.

These cases were treated by the use of heroic doses of cinchonidia, or quinia, every evening, *i. e.*, grains x to xl, according to the ages and strength of the patients, also with the fever mixture commended by Bartholow, *i. e.* tinct. iodine and carbolic acid, by as nearly continued bathings as possible, cold drinks, *ad libitum*, and as the strength failed or the fever gave way, some form of alcoholic stimulant was given, and finally the free use of digitalis, as the weakness of the heart became manifested. Food was regularly given. In the first case, life seemed so near extinct at one time that the hypodermic use

of ammonia was resorted to, and also, by the same method, whisky and atropia. After rallying, stimulants alone were relied upon in connection with nourishment. In the last case atropia was often resorted to to rouse the circulatory and respiratory centres, also nux vomica. But the main line of treatment was pointed out above. Of course, nourishment was carefully attended to, and kept up with great care and precision throughout the whole course in each case. No fatal results occurred in any of these cases.

Typhoid fever was not epidemic in this locality. There had been cases here and there for more than a year, but not many of them, and few of them of the low, severe form. Therefore we believe that epidemic influence had nothing to do with the production of these cases. No case of typhoid fever had ever occurred in the house where this family resided, for it was quite a new house and its history is well in hand. Reasoning by exclusion we find no other cause than that of the water on the one hand and the malarious air from the adjacent flats covered with foul sediment from the back-water, coming, as it must, up the foul creek, and taking into solution the debris from the cattle and hog pens on its banks. A strong reason for suspecting the drinking water was the fact that while all the other families in that immediate vicinity were exposed to the same general causes, none of them were subjects of the disease except this one, this being the only family using water from this cistern. I know it is not easy to trace the source of the poison in these cases, and therefore do not claim to fix its origin with any certainty.

The points of interest in these cases are—

1st. The regular succession of them, one following the other at quite regular intervals as to time of attack.

2d. The very marked high temperature in two of them, and the long continued high fever in one.

3d. The case of "walking typhoid," with its high and regular course of typhoid temperature while still up, eating well, playing, running errands, etc.

4th. Perhaps I may note the great value of the hypodermic use of stimulants in the extreme condition in the first case.

—An English Slaughterman makes the statement that but few calves have perfectly healthy livers, "not one in ten," most of them containing larger or smaller collections of putrid "matter."

Hospital Reports.

PHILADELPHIA HOSPITAL.

A CLINICAL CONFERENCE BY JOHN M. KEATING, M.D.

Reported by W. A. Edwards, M.D., Assistant Pathologist to the Hospital.

The Scrofulous Diathesis.

Gentlemen:—We will to-day study scrofula, which may be defined as a diathesis, characterized by disorders of the nutritive process, whereby the tissues are permitted to undergo inflammation from trifling irritants; by hyperplasia of certain parts, more particularly the lymphatics, and especially the glands of that system.

The inflammation is more apt to be of a subacute character, and its products are prone to cheesy degeneration. It is a disease of infancy and childhood, as you can see by the number of its subjects in this ward, rarely presenting its first manifestations in adult life. Scrofula may be either *congenital* or *acquired*: in the former it is seen in children of scrofulous, aged or nearly related parents, or in tertiary syphilis, tuberculosis, etc., of the parents, more especially of the mother, or again, from prolonged lactation from other children, rapid child bearing, or feebleness of the mother.

In the latter, the acquired, it is developed after birth, from a predisposition brought about by cachectic parentage. Artificial feeding or insufficient nourishment may be set down as a frequent cause, as are cold, moist, badly ventilated, sunless abodes, little movement of the body, preceding severe sickness or exhausting diseases in the first months of life, as the eruptive fevers, measles, scarlatina, pertussis, etc.

It can be transmitted by inoculation, and, in fact, it has been stated by some well-known experimenters, that the inoculation of tubercle results in the development of scrofula, and more recent investigators have demonstrated that there is no essential histological distinction between tuberculosis and scrofulosis of the lymph glands.

This resemblance is further borne out by the frequently simultaneous occurrence of tuberculosis and scrofulosis, and from the fact that scrofulous children not infrequently become tuberculous. The scrofulous new formations resemble the tuberculous, not only in themselves, but in their metamorphosis, cheesy degeneration, or simple atrophy.

Scrofula is frequently torpid or latent, as it was in this little baby, requiring an irritant to develop the primary symptoms. In this case vaccination was followed by all the manifestations of scrofula. It is scarcely, then, well for us to state that scrofula is contagious; but, as we said above, direct inoculations may produce it in one predisposed.

As vaccination, when carelessly done, is the readiest means for this transmission, either by producing simple inflammation and thereby awakening into activity the scrofulous diathesis, or the direct transmission of the blood or inflammatory products from a scrofulous child to another untainted; hence, we should be on our guard.

Symptoms.—The diathesis usually develops or shows itself first upon the skin or mucous membranes, then the contiguous lymphatic glands, though at times periosteal lesions, or those of bones, may occur primarily.

If you will glance around the ward you will notice a number of children presenting scrofula in its various lights and stages.

This little one shows the various skin inflammations and eruptions of the disease, especially on the head and face, chiefly in the region of the nose, mouth, eyes and ears, mostly of an impetiginous or eczematous form; the latter is a very common eruption; it also illustrates well a scrofulous inflammation of the eyes, *i. e.*, phlyctenular keratitis. Conjunctivitis is usually seen in these scrofulous children.

Now if we turn to this patient we find the cervical lymphatics enlarged and well marked; this is of the character of a cellular hyperplasia, and sometimes we see the simultaneous formation of pus, or again, we may have the deposition of miliary tubercles.

These enlargements are of varying sizes; some are hardly visible, others the size of a pea or larger, and again others involve the whole gland. Cheesy degeneration is very prone to occur with suppurative inflammation around it, leaving ulceration and finally a permanent cicatrix, as we see in this woman's neck, the mother of our patient.

Otorrhœa and caries of the bones of the ear is an early and not infrequent manifestation of the diathesis, as these two little infants show us. A frequent symptom is inflammation of the bones and the joints—occasionally only of the periosteum, generally of the bone itself—which not infrequently terminates in caries or necrosis; this is most seen in the vertebræ or the small bones and joints of the extremities, especially the lower.

We occasionally see strumous dactylitis occurring in these children of a year or more, of whom we are unable to obtain any syphilitic history whatever. There is no peculiar anatomical characteristic of the individual affections of scrofulosis, nothing in the tumefaction of the glands, except their sluggishness; these non-inflammatory swellings are more like chronic œdematous infiltrations, occasionally more like œdematous connective tissue hypertrophies.

Characteristics of it, however, are the great ease of its appearance, in other words, the great vulnerability of the tissues, its sluggishness, its mostly persisting for years, its return without apparent cause, the ease with which the lymph glands take part and the length of time that suppuration of the latter outlasts the primary affections of the skin and mucous membranes.

The scrofulous diathesis may be exhibited in children whose features and forms are delicate, whose skin is transparent, and who are easily excited, with bright eyes and good intelligence, the so-called *erethistic* scrofulosis; or again, in those who are large and flabby, languid in movements, in whom an over production of fat is seen, especially in the nose and upper lip, the so-called *torpid* scrofulosis.

Scrofula and leucæmia are not identical, the first occurring usually in childhood, the second in manhood; the first being usually accompanied, in its advanced state, by diminished corpuscles and increased water, and only when in the state of inflammatory enlargement of the glands does it simulate the latter in having an increased number of white corpuscles.

The *prognosis* in the lower grades of the disease, with care, is good; in the more severe grades it not infrequently terminates in death; the latter result is generally brought about by tuberculous or scrofulous suppuration, or by miliary tuberculosis of internal organs, severe joint and bone suppuration, and, hence, marasmus, or again, by lardaceous degeneration of the various organs. We rarely see a scrofulous subject die through general anæmia.

The *treatment* should be prophylactic and curative; for the former we should avoid all those causes that I laid down as factors in acquired scrofulosis

We should see that our little patients who present this diathesis have plenty of warm clothing, fresh air and sunlight, occasional trips to the sea-side, with salt baths, etc. We should also see that their diet is carefully regulated and nutritious; an important article of the dietary is good, rich milk. The digestive organs should receive a large share of your attention. See that they are in perfect condition and maintain them so, if possible. You should order a proper amount of physical exercise, with little mental labor.

For the *curative* treatment our sheet-anchor is cod-liver oil, iron and iodine; the two latter may be combined as the syrup of the iodide of iron, or you may use the tr. ferri chlor. An important reinforcement to the cod-liver oil is the lacto-phosphate of lime. Tonics should not be given until you have corrected all evidences of marked intestinal derangement. Alcoholic stimulants must be used in moderation. I prefer the light wines or malt liquors to the stronger stimulants. Local ailments should be especially attended to. For glandular swelling you may use iodide of pot. ℥j, ung. stramon ℥j, or the ointment of the red iodide of mercury.

For the conjunctivitis I use atropia sulph. gr. ij–℥j; when phlyctenulæ occur you may dust with calomel.

The various skin eruptions, bone affections, etc., attendant upon this diathesis, need but little modification of your general plan of treatment.

Rœtheln and Morbilli.

We have before us the study of an eruptive disease, in fact, *two* of them, and I wish to call your attention to their distinguishing features.

These children are Swedes; they have just come from shipboard, where they have been exposed to the contagion of an exanthem, and also to the depressing influence attending a sojourn in the steerage. There have been a number admitted to this house, some with the eruption already at its height, others presenting simply the prodromic symptoms to be shortly followed by the eruption as you see it.

Let us study this little sturdy fellow. You will notice that he is covered with the eruption, and that it presents these characteristics:—

Upon the forehead it is almost uniform, of a

somewhat salmon color, not raised above the surface, but readily disappearing upon pressure; as it approaches the temples, islands of surface appear unaffected; the shore lines, if I may so term them, have a distinct crescentic character; you will also note that as the eruption spreads over the face it gives a decided blush of uniform redness to the cheek, of a rather darker color, bordering on a shining, crimson appearance.

Again it extends down upon the neck, with a more punctiform appearance, but still not raised to any very appreciable extent, in fact, looking more as if the color had been washed in by an artist. Let me call your attention, in passing, as the child turns its head from you, to the fact that you see distinctly the outline of the facial bones; in other words there is little or no œdema of the face.

I also call your attention to the fact that the eyelids are not swollen, there is but slight conjunctival redness, in some cases none at all, as is the case with intolerance to light.

The eruption in the soft and more delicate parts, as the chest, axillary region, inner forearm, the groin, and the site of the outer tibial muscles, bears a close relationship to that of the face.

In this it is said to resemble scarlet fever, though I must confess I do not see the similarity. Upon the coarse skin you have a coarse eruption, distinctly papular, scarcely raised, and attempting to form large crescents, "rising moon"-like in appearance. Here we note that the eruption is darker in color, bordering upon a purple.

The throat is red, of uniform redness, not punctiform, and the tongue, like scarlet fever, is *ermine* like.

The history given us is one of five days of prodromic symptoms and malaise. There have been sneezing and coryza, with a sore throat; a febrile tendency and a clear, ringing cough. There has also been, and there is at present, distinct enlargement of the cervical and post-cervical lymphatic glands.

In adults these give rise to stiffness of the neck and radiating pain down the back and upward toward the occiput. In this case there is but slight bronchial catarrh, even though the eruption is at its height, and the cough is paroxysmal, as you notice, and still croupy.

This eruption will last four days or less, and rapidly disappear, with no desquamation of the cuticle, but some stains will remain, which resemble the petechiæ of typhus fever, and last for a few days. This boy's temperature is now about 103°, but it will rapidly fall; the rapidity of cure is remarkable.

There have been some cases in this ward which have developed a severe bronchitis, and yesterday an infant died of complicating croupous pneumonia; this is a rare termination, and attributable to the exposure on shipboard, exhaustion from the sea voyage and close confinement, more than to the disease itself.

Now, what are the principal points to be noted? First, the character of the eruption; the absence of swelling of the subcutaneous tissue, especially of the face; the absence of marked conjunctivitis; the decided enlargement and tenderness of the post-cervical glands. I may remark that I deem the laryngeal cough, which remains *croupy*, as to be specially noted, and the marked absence of severe bronchitis with a loose cough shortly after the appearance of the eruption, which in measles shows that the mucous membrane has been affected as well as the cutaneous surfaces. The sudden cessation of the symptoms, disappearance of the rash and the absence of scaling of the cuticle.

Let us now study another epidemic which we have in the children's asylum.

This little girl, whom I show you, is two and a half years old; has been an inmate of the house for some time.

Several days ago she began to ail, suffering from a "severe cold in the head," with conjunctival redness; an examination of her throat showed an inflammatory action, with a decided punctiform or papular condition of the mucous membrane of the anterior half arches and of the uvula. There was also some enlargement of the tonsils and tenderness of the glands, also of the lymphatics at the angle of the jaws.

The next day there was a decided rise in temperature, with an aggravation of the symptoms, decided photophobia and swelling of the eyelids.

An indistinct eruption appeared on the temples, very pink in appearance and crescentic in form, like minute pin points in small crescents.

This faded away, to develop the next day with greater distinctness. The following morning she had a high temperature, 104°, the face was swollen, the eyes fiery red and almost closed; a profuse eruption was now on the cutaneous surface resembling that I have just described. There were no blotches, no even redness, but throughout it was papular, raised above its surface, and evenly crescentic. At this time the cough became frequent and the secretions of mucus from the laryngeal and bronchial membrane, like that of the conjunctiva and nares, was profuse.

It was a loose cough. The chest and arms resembled the back in appearance, but the back and nates, part of the thighs and buttocks, showed a coarser eruption, in regular ridges, decidedly papular. The bowels were also slightly distended, and there was at times nausea.

To-day you see the eruption at its height, and I call your attention to its color as well as to its other qualities that I have described. The color is now of a flesh-pink, though darker on the thighs and buttocks, being there more of a salmon color.

Now in this case you have evidences of marked bronchitis; you hear coarse and fine mucous râles; but I am happy to say you can detect at present no evidences of catarrhal pneumonia. It is needless to say that here we have a type of *measles*, and the marked contrast of these cases which I have shown you cannot be questioned.

We see our little patient to-day at the "cross-roads" of the disease. It may result in a gradual amelioration of the symptoms, with gradually lessening fever, a deeper-colored eruption, the gradual fading and subsidence of the œdema, and finally the desquamation of the cuticle in branny scales; or again, she may develop symptoms more typhoid in character, symptoms of malignancy, with croupous exudation in the throat, diphtheritic in appearance,

and, in fact, finally, death from blood-poisoning, with, in all probability, convulsions; or again, catarrhal pneumonia may develop and carry off our little patient in a few days.

I have shown you lately several cases of these forms, and you have studied their post-mortem appearances. You have, then, to tabulate the peculiarity of the eruptions; first their *seat* of appearance, its colors and its distinct papular (elevated) crescentic appearance; also the marked coryza, with swollen eyelids, and the conjunctivitis, upon the appearance of the extensive bronchitis with much secretion (a soft cough.) You have but little swelling of the lymphatic glands. In addition, you have had the punctiform sore throat, the prolonged stage of eruption, with the gradual fading and the marked desquamation of the cuticle. In addition to these you have the *complications* which are so numerous in measles and so rare in rötheln.

What is the treatment?

You have already noticed that I have laid great stress on the *complications* in discussing the future of these cases, and I may further add, that apart from the usual treatment of a febrile attack, the concomitant complications alone need attention; first to avert them, and secondly, to modify their severity. Rötheln, apart from these, which, as a rule, are not frequent, except in children previously exposed, is a mild disease, requiring only hygienic measures in its treatment; but *measles* in children who are strumous is an exceedingly fatal disease, especially in hospital and alley practice.

First you have the tendency of bronchial catarrh to extend and develop catarrhal pneumonia, and secondly, you have typhoid and diptheritic forms to contend with.

For the former you will find the counter irritation of warmth and moisture most important, with the administration of small doses of quinia during the day and bromide of potass., ammonia, or Dover's powder at night; the latter is especially efficacious.

You can give a fever mixture of citrate of potass., with the citrate of ammonia, and milk or chicken broth, at regular intervals.

I prefer the use of *hops* quilted in between layers of flannel and steeped in hot water, instead of poultices, covering it well with oiled silk, to prevent evaporation.

For the latter the most energetic tonic and stimulant treatment is required early in the attack, carbonate of ammonia, quinia, the vegetable acids, and alcohol, in large doses. The frequent use of hot baths, 98°, should any cerebral symptoms develop; a careful regulation of the nourishment, so that the child will take a suitable quantity at short intervals and in small amounts.

I am a firm believer in calomel in small and repeated doses, and alcohol in large amounts, when *diphtheritic* exudation or symptoms of malignancy show themselves.

I have also confidence in the external application of vaseline, which gives softness to the skin, aids in the reduction of temperature, and frequently gives a quiet night instead of the usual restlessness that accompanies cutaneous irritation, with a hot, dry skin.

Medical Societies.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, June 1st, 1882. The President, Dr. Edward L. Duer, in the chair.

Dr. B. F. Baer related the history of a case of **Punctured Wound of the Pregnant Uterus; Partial Escape of the Fœtus into the Abdominal Cavity; Retention of the Fœtus Five Years.**

October 4th, 1881, Catherine Curley presented herself at the Dispensary for the Diseases of Women, at the Hospital of the University of Pennsylvania, and gave a history which is essentially embodied in the following letter, addressed to Dr. Goodell from her physician, Dr. John Keogh, of Killaloe, Ireland. (This letter was received after the patient had been treated as described in this paper, but as it gives an intelligent description of the case at the time of the accident, it was thought proper to insert it here.)

"Catherine Curley, who was within a week of her confinement, was standing upon a chair, the back of which, with the exception of two uprights, had been broken away. She was at the time collecting brambles, and in stretching for one over reached herself and fell, and in the act of falling her right side came in contact with one of the uprights. A short time after she was found lying on the ground in a fainting condition, from which position she was removed to bed and I was summoned to see her. On examination I found a contused wound on the lower and right side of the abdomen, and in addition came to the conclusion that the womb was ruptured and that the fœtus had escaped into the cavity of the abdomen. There was intense tenderness and great distention. I immediately decided on giving her at once calomel and opium, the latter in large doses. After the third day I stopped the calomel and continued the opium. The pain and tenderness almost disappeared after a week, and I may say, from that period until she left here she never had a bad symptom.

"Several medical men in this county expressed doubts about the correctness of my diagnosis, but I at once convinced them by presenting the woman for examination at Limerick, a city near here, where many men of eminence and long experience saw her."

Dr. Keogh does not say that the prong of the chair was driven into the abdomen. It appears, however, that such was the fact.

It would seem incredible that the pain and tenderness should have almost disappeared in a week, and that she should not have had a bad symptom until five years had elapsed. She, however, recovered from the accident, and, strange to say, menstruated three months afterward, and has been doing so regularly ever since. To make matters worse, if possible, her husband, who was in the last stage of phthisis at the time, died within a week, and she was left, without means, to support a family of five small children. This she did through four years, by manual labor. Three years ago she came to this country and settled in Salem, N. J., where, last summer, she was under the care of Dr. E. C.

Sharp, at which time she passed through an attack of what seemed to be typho-malarial fever, in consequence of which she became somewhat emaciated and her muscles became relaxed and toneless. This allowed a hernial protrusion through the puncture in the abdominal wall; for this she sought relief, hoping to procure a suitable truss. I only obtained the history of the accident by direct questions in regard to the cause of the hernia, that being regarded by the patient as the greater difficulty and the one requiring treatment. Physical examination, with the patient in the dorsal position, revealed, by palpation of the abdomen, a circumscribed mass in the hypogastric region, extending as high up as the umbilicus and a little further to the left than to the right of the median line. It was about the size of the pregnant uterus at the sixth month, rather flaccid, and pressure on it gave to the hand the sensation of loose bones moving over each other, a kind of crepitus. On the right side of the abdomen, a little below the umbilicus, there was a round perforation about the size of a silver dollar, which seemed to penetrate everything except the skin. Through this break in the abdominal wall the intestines protruded when she was upon her feet, constituting the ventral hernia, for which she desired the truss. Examination *per vaginam* gave the following result: The cervix-uteri was small, hard, rather low down and pointing forward, in the direction of the vaginal orifice. The os externum was small and circular, but it was patulous, and flowing from it was a peculiar yellowish fluid, slightly fetid. The finger carried posterior to the cervix discovered the body of the uterus enlarged and apparently expanded around the loose bones referred to above. Now, carrying the finger to the anterior surface of the cervix, the same bulging forward was discovered and the same continuation of the anterior wall of the cervix into what appeared to be the anterior wall of the developed uterus. Bimanual examination seemed to confirm the opinion already forming, that the fetal remains were still, in part at least, within the uterine cavity. On the right side of the uterus, near the fundus, there was a prominence; otherwise the walls were smooth. I now passed the sound through the os and into the uterine cavity, when it came upon a mass of bones, which seemed to be loosely held together by disintegrating soft tissues. The instrument was readily passed to a depth of six inches, and could be moved about with the greatest ease and without the least sensation of pain to the patient; its withdrawal was not followed by any discharge. There was nothing about the case which led me to suspect even that the sound had not really passed into the uterine cavity, but instead, that it might have passed through an opening in the uterine wall near the cervix, into an extra-uterine cyst containing the fetal remains. It may, however, have passed through the opening which was afterward found near the fundus, but not before meeting with that portion of the remains surrounded by the expanded but flaccid uterine walls.

I was, naturally, I think, rather inclined to disbelieve the history of rupture of the uterus, from such an accident, to a degree sufficient to allow the child to escape into the abdominal cavity, since the subject was alive and before me. I sought to explain the unusual condition by one of the following hypotheses, viz.: first, that the pregnancy had been an extra-uterine one, and probably of the interstitial variety; that the accident resulted in the death of the child merely, and not in the rupture of the gestation sac. That it had then remained a harmless body until the patient had become reduced by the fever noted above, when it began to disintegrate, from decomposition, and be driven off per vaginam, after first ulcerating its way through the uterine wall into the cavity of the uterus; but this could not have been so, and the physical condition set down as the result of my examination exist. Second, that it was one of those very rare cases of so-called missed labor, in which, for some reason, shock of an accident, for instance, by which the nervous system is so depressed that there is not power enough to cause uterine contraction, the product is retained indefinitely within the cavity of the uterus. Third (and considered the correct explanation), that the uterus was really ruptured, but that a portion of the child escaped through the rent, thus preventing by pressure a loss of blood which would otherwise have probably resulted in the death of the patient, and that the portion which projected through the rupture became encysted, thus forming a cavity continuous with the uterine cavity, the whole mass remaining harmless until, through intercurrence of an exhausting disease, decomposition set in and it began to poison the patient. It is not necessary to offer an explanation, if the latter hypothesis be correct, why the uterus did not contract and expel its contents; because it is well known that in the event of rupture occurring during labor the pains immediately cease. But in any event expulsion could not have been accomplished here with the child held fast in the rent. Then, I think, the fact that the patient came so readily out of the collapse and recovered so quickly, and that the child lived so long (it is said to have lived three days), prove pretty conclusively that there was no great blood loss, and that the child did not escape entirely from the cavity of the uterus. The child dies very soon after it is expelled into the abdominal cavity, for two reasons, viz.: maternal hemorrhage, and interference with the function of the placenta and cord. Hemorrhage did not occur, if my theory is correct, for the reason stated above, and the functions of the placenta were not interfered with at once, because it was not separated from the uterine wall suddenly, nor compressed, as would have been the case had the uterus been empty and contracted.

My advice to the patient was that she submit to an operation for the removal of the decomposing mass, as I considered that she was suffering from slow septic absorption. The operation I suggested was dilatation of the os uteri and removal of the dead product *per vias naturales*. This I looked upon as the most feasible operation, for the reason that it seemed to be of such easy access through that channel, and therefore the one which would be attended with the least amount of danger. Removal by

laparotomy would have been most hazardous, since it would have been necessary to open the cyst and therefore the old rupture of the uterus. There would have been a fistulous opening in the uterine wall, which would have been closed with difficulty if at all. Moreover, the sac would very likely have ruptured, thus precipitating the contents into the peritoneal cavity. This, of course, would have been a grave complication, as the decomposing material would have been removed with difficulty and danger. Against removal through the os uteri was the possibility, if not probability, of rupture of the sac containing that portion of the fœtus outside the uterus, and expulsion of the contents into the abdominal cavity. This might have necessitated laparotomy, for the cleansing of the peritoneal cavity.

The patient, however, refused at that time to have the operation performed, and returned to her home.

December 16th, 1881, she again presented herself at the Dispensary, and exhibited undoubted evidence of septic absorption, in rapid pulse, evening rise of temperature and night sweats. Examination now showed the mass to be much lower in the hypogastrium, and apparently smaller than at the previous examination. The cervix was, however, of the same length and still hard, with no tendency toward dilatation of the os. The sound revealed the dead product to be nearer the os, and, altogether, this examination served to confirm my former opinion, that the product was largely contained within the uterine cavity, and that it could be removed through the os and vagina. This opinion was strengthened by the fact that there had been evident contraction of the walls surrounding the mass. She still refused to submit to the operation, and returned to her home. Her health continued to depreciate, and she was glad, on January 3d, 1882, to enter the gynecological ward of the Hospital of the University, in charge of Dr. Goodell.

After careful examination, Dr. Goodell confirmed, in the main, the opinion expressed above as to diagnosis and treatment, and two days later introduced into the os uteri one sponge and four laminaria tents. Next day the patient was anesthetized and the tents removed, when an effort was made to remove the fœtus. A fenestrated polypus forceps was passed into the cavity and made to grasp the contents; this was readily done, but the removal was not so easily accomplished, for when traction was made it was found that the fœtus was held firmly somewhere, and that it was so disintegrated that only the portion within the grasp of the forceps could be withdrawn with the instrument. This was repeated a number of times, each withdrawal of the forceps bringing away a bone or some broken down soft tissue. A discharge of about a pint of very fetid, thin fluid took place at this stage of the operation. The os was now becoming so small, from contraction of the cervix, that the forceps could scarcely be made to pass, and an effort was made to secure further dilatation by the use of Molesworth's dilator. But it would not work, because it was out of order, from long disuse. The only thing left to do was, either to introduce another set of tents and wait until they had dilated the cervix sufficiently, or incise the neck to the vaginal junction. The latter was done. The danger of septic absorption from such a proceeding was fully considered, but it was decided that to introduce another set of tents, let the patient come out of ether, and wait for their slow dilatation, would be the greater evil. Before and after the incision the parts were thoroughly disinfected by injections of a permanganate of potash solution. The same polypus forceps were now more readily introduced into the cavity and the mass broken up. This was followed by a profuse, thin, bloody, purulent discharge, of the most fetid character. An injection of the permanganate solution was now made, into the cavity of the uterus, until it returned unchanged, when another effort was made to remove the contents. After working for more than half an hour only a part of the product was withdrawn. At this stage of the operation considerable hemorrhage occurred, and this was increased with each endeavor to dislodge the mass from its nidus. For this reason, and because the patient was becoming weak (she had now been under ether one and a-half hours), it was thought prudent to discontinue further efforts for the present, and to depend upon antiseptic injections and contraction of the uterus to remove the remainder; or at least, to allow the patient to recover from this desperate condition, and gain strength to stand a second effort, after the mass had undergone further disintegration. There was, also, a fear of rupturing the cyst containing that portion outside of the uterine cavity, by further efforts.

The patient came out of the anesthesia slowly and in a state bordering on collapse, in which condition she remained for nearly twenty-four hours, when she gradually reacted. During the next four days there was a very fetid fluid discharged from the cavity of the uterus, together with some debris from the decomposing mass. The patient had to be removed from the ward, on account of the odor. The treatment was supporting, with very frequent irrigation of the vagina and uterine cavity with antiseptic solutions.

On the fifth day after the first operation, the patient evidently suffering from septicæmia, and there being no marked effort on the part of the uterus to throw off the remains, she was again etherized and another attempt was made to remove them. It was found that time had somewhat disintegrated the contents, and that, therefore, removal would be more easily effected. Bone after bone, and occasionally a piece of soft tissue, were withdrawn, until, at the end of about an hour, the cavity was almost entirely, emptied. I say almost entirely, because it seemed impossible to to get every small bone away, and for several weeks afterward an occasional bone would be thrown off per vaginam. The cavity was thoroughly washed out with the disinfecting solution and an examination made, to discover the seat and extent of the rupture.

The cavity of the uterus was large and rough, and in the right side of its body there was discovered an opening, through which two fingers could be readily passed into a cavity beyond.

The recovery of the patient was slow; indeed, her life was despaired of for weeks, during which

time she suffered from numerous pyæmic abscesses. One of the abscesses was post-ocular, and resulted in the loss of the eye. She finally left the hospital, restored to health.

Removal of a Mammary Tumor and of Enlarged Axillary Glands—Primary Union.

Dr. W. H. Parrish exhibited the specimens and the following history: The patient from whom the specimens presented were removed is a lady of very slight stature, sixty-two years of age, and the mother of several children. There is no history of cancer in her family.

About twenty-five years ago she noticed a hard lump in the axilla, about the size of a partridge egg, painless, though tender on pressure. It was first noticed during a period of lactation; subsequently she was again confined and passed through the usual time of lactation, with a slight increase only in the size of the axillary tumor. For about twelve years after the first appearance of the axillary tumor she never noticed a lump in the breast. About twelve years ago, however, she, for the first time, recognized the presence of a mammary mass, then about the size of a partridge egg. This was about the menopause; at that time she lost in flesh, though her general health remained good.

The mammary tumor increased in size very gradually; continued free from pain, except when something would press unduly against it. About twelve months ago she thought the tumor had begun to increase in size a little more rapidly, and occasionally gave a sensation of soreness. This change in the tumor was ascribed by the patient to carrying in her arms a grandchild.

At the time of the operation the tumor in the breast was about the size of a small lemon, very hard and somewhat nodular, and was at the upper and outer border of the gland. It was perfectly movable over the pectoral muscle, and presented a distinct elevation above the general skin surface. The skin was not entirely movable over the mass, but was not hardened or otherwise altered in character. There was no nodular involvement of the integument. The superficial veins were not enlarged. The nipple was not retracted, seemed entirely normal, and no fluid could be pressed out of it.

There were three enlarged axillary glands, the largest very hard and a little larger than a partridge egg. There was no enlargement of the glands above the clavicle. Owing to the long duration of the masses, their entire mobility, the freedom of the skin from nodular infiltration, the absence of retraction of the nipple and of oozing from it, and also owing to the evident atrophy of the mammary gland, I concluded not to remove the entire breast, but only the tumor, including those of the axilla, and to remove also the integument overlying the mammary tumor. This I effected by an elliptical incision, and then extending the incision to the axilla, removed three enlarged lymphatic glands. It was not necessary to ligate any vessel; the oozing, which was not great, was stopped entirely by the use of hot water. The incision was about seven inches long. The edges were approximated by deep silk sutures. A few strips of rubber adhesive plaster were applied, and all covered with a layer of salicylated absorbent cotton, and the chest surrounded with a flannel binder. This entire dressing was allowed to remain until the fourth day, when, on removal of the cotton, it was seen that primary union had been secured throughout the entire incision. There was neither hardness nor swelling, to indicate inflammation. On the sixth day the sutures were removed, and on the tenth day the patient sat up. No medicine of any kind, not even an anodyne, was given during the entire treatment.

The long duration and small size, the normal appearance of the nipple, the freedom of the skin from pitting and nodular infiltration, and the mobility of the mammary tumor over both the pectoral muscle and on the mammary gland, have led me to hope that the growths are fibromata; but the enlargement of the axillary glands and their induration make me fear carcinoma.

Microscopical Examination by Dr. Henry Beates, Jr.

The specimen presented by Dr. Parrish is of unusual pathological interest. When it is remembered that the growth was present for nearly thirty years without undergoing a noticeable change, and only during the last year occasioned suffering and was accompanied with axillary involvement, the question of malignancy suggests itself, especially as the clinical history almost forces the diagnosis of adenoma. As many representative pathologists incline to the belief that typical mammary adenomata do not undergo carcinomatous degeneration, and many assume a conservative or non-committal position, this instance is of unusual interest and demands close study. Sections were made through the mass, and including the cutaneous surface. The skin, so far as the striatum corneum and rete-mucosum are concerned, is normal, but in the corium are areas of inflammatory changes. The radicles of several of the vascular papillæ are choked and surrounded by numerous embryonic cells and inflammatory corpuscles. The larger vessels are in a like manner involved, and the tissue in their immediate proximity infiltrated. The pons reticularis, where it becomes continuous with the subcutaneous connective tissue, is, in many places, the seat of proliferated connective tissue corpuscles.

The *glandular structure* shows beautifully its purely adenoid character. The acini, although filled with cells and almost hidden from view, are, with care, easily distinguished. The inter-acinous connective tissue is hyperplastic. The hyaline membrana propria is partially destroyed, and the acini filled with degenerated epithelial cells and cellular elements of increased size, possessing many nuclei. Some of the acini have the membrana propria entirely destroyed. The lymph spaces are occluded by cells, multinucleated and of increased size and irregular contour. The inter-acinous fibroid tissue presents incipient formation of stroma and aggregations of cells.

The axillary gland is completely altered in its structure, and instead of the mass of lymphoid cells, occupying large spaces bounded by the characteristic fibrous stroma, with its triangular basal form, we have typical carcinomatous structure. Fibroid stromata, joining at acute angles, forming numerous interspaces filled with irregu-

lar multinucleated cells, characterizes the degenerated gland as carcinomatous. This fact, in conjunction with the changes seen in the mammary gland, prove conclusively that the breast tumor was originally a typical adenoma, which, after thirty years, began to undergo malignant degeneration, and became a centre from which the axillary glands were infected. Dr. Robert P. Harris remarked that a point of great interest in the history of this tumor was the long period during which it remained dormant. He had had under observation a case in which a mammary tumor had remained perfectly dormant for seventeen years, during which two pregnancies occurred. After the second labor the tumor commenced to enlarge and become painful. An operation for its removal was performed some months later, when it had attained the size of a duck's egg. A chain of nine enlarged glands was removed with the tumor. The tumor recurred in the same breast and was followed by one in the other breast and numerous hard, nodular growths, over the entire body. Her death was due to this cause.

Two aunts of this patient, living in the South, had died of cancer. A sister had a tumor in the abdominal wall, which was allowed to attain the size of a door-knob without interference. At that time Dr. Agnew and other surgeons were opposed to the advisability of an operation. After a year the tumor commenced spontaneously to discharge a purulent matter. It was then successfully removed by Dr. Agnew, who pronounced it an encephaloid growth. It had made no attachments to the underlying vital tissues, and has shown no sign of returning. Two years have elapsed since the operation.

The Physics of Nerve-Stretching.

Dr. J. Symington, in the *British Medical Journal*, after detailing a number of experiments, gives the following conclusions:—

My experiments clearly show that the great sciatic nerve is able to withstand a considerable strain; but they also indicate the necessity for caution; more especially in the downward traction of the nerve. I have several times attempted to break this nerve in the dead subject, but have invariably failed, although the nerve was greatly stretched, and I sometimes heard suspicious crackling noises. The suggestion of Dr. John Cavafy, in the *Journal* (December 17th, 1881), that surgeons should come to some more definite idea of the amount of force employed, should certainly be acted upon. There are several points in connection with the operation of nerve-stretching, which have not apparently been sufficiently considered. If a nerve, such as the great sciatic, having an almost direct origin from the spinal cord, be pulled downward, an anatomical examination will show at once that almost the entire strain is borne by the dura mater. If the vertebral canal be opened from behind, so as to expose the spinal dura mater, and at the same time the great sciatic be stretched, a slight downward movement of the lower part of the dura mater is at once visible. By careful measurement, however, I find that it is not displaced more than an eighth of an inch. The dura mater possesses very little extensibility; and, further, the nerve-roots piercing it nearly opposite the intervertebral foramina, the stretching of the great sciatic rather tends to displace the dura mater laterally. Even a cursory examination will at once show that this cannot occur to any appreciable extent. If the dura mater be opened in the lumbar region, and the roots examined, it will be evident that the slight displacement produced by the stretching of the dura mater can have no appreciable effect in increasing their tension, and thus enabling them to act directly upon the spinal cord. The dura mater thus serves as a very efficient protector of the delicate spinal nerve-root; but, should it be torn, an extremely small force would suffice to detach them from the spinal cord. It therefore appears evident that stretching a nerve, such as the great sciatic, produces no direct mechanical action upon the spinal cord. Stretching a nerve less directly connected with the spinal cord, such as the median, is still less likely to affect directly the spinal cord; and, of course, there is no danger, in case of rupture, of its being detached from the cord. In the few experiments I have made upon this nerve, it always broke at the point where the force was applied.

The manner in which a beneficial effect is produced by the operation of nerve-stretching is very obscure. In some cases of sciatica, it may be due to the breaking up of adhesions, etc., pressing injuriously upon the nerve. In cases of central lesions, it probably acts upon the same general plan as other counter-irritants.

There is abundant clinical evidence to show, as one would expect, that the operation of nerve-stretching produces a powerful local action—not unfrequently being followed by temporary paralysis. Then, again, it produces a marked effect upon distant nerve centres, such as the respiratory and cardiac, as is shown in Langenbuch's cases. As a counter-irritant, it stimulates, not merely the nerve, but also its connecting trunk and branches.

In the operation, many surgeons attach special importance to the downward traction of the nerve—apparently believing that, by this means, they produce some direct mechanical action upon the spinal cord. This appears to me, as I have before stated, to be an erroneous idea; the nerve-fibres, as far up as the dura mater, being put

upon the stretch, but not the spinal nerve-roots beyond.

Dr. John Cavafy, in the *British Medical Journal* (December 17th, 1881, page 974), objects to the "nerve-stretcher" of M. Gillette, partly on the ground "that the extension must affect the peripheral and central portions of the nerve itself." If my view be correct, this is rather an advantage than otherwise, as a longer tract of nerve fibres is thus stimulated. Furthermore, by stretching a loop of the nerve, the force is divided between the peripheral and central ends—so that there is less liability to rupture. Traction upon the peripheral end of the nerve can be employed with more safety than upon the central end, the former being the stronger; and the nervous stimulation would probably be as great, if not greater.

Nitrite of Amyl in Hour-Glass Contraction of Uterus.

Dr. Fancourt Barnes records the following case in the *British Medical Journal*:—

I was called, at ten o'clock in the morning, on February 28th last, by one of the midwives of the Royal Maternity Charity, to a patient with retained placenta. On my arrival, I found that the patient, a secundipara, aged 22, had been delivered naturally, at three o'clock in the morning, of a living female child. The midwife stated that she sent for me because she had been unable to deliver the placenta. On examination, I found that the umbilical cord had been separated from the placenta. The external os uteri was quite dilated, as was the cervical cavity; but the os internum and the circle of muscular fibres above it, called Bandl's ring, the chief seat of hour-glass contraction, were firmly contracted, and only admitted a finger, by which the placenta could be felt in the uterus. I now learned that the midwife, hoping to accelerate the third stage of labor, had given the patient a dose of ergot as soon as the child was born. I found it impossible to get my hand into the uterus to deliver the placenta. Bearing in mind the remarkable power which nitrite of amyl possesses in relaxing tension in the blood vessels, I determined to test its action on the uterine spasm. The patient had three drops of the nitrite of amyl given her on a handkerchief, to inhale, by Mr. Lingard. During the inhalation, the ring of muscular fibres round the os internum, which had been so rigid as to be absolutely undilatable, steadily yielded, until I could pass the whole hand into the uterus and detach the placenta, which was universally adherent. There was no hemorrhage whatever, and the placenta itself presented a remarkably exsanguine appearance. On referring to the third edition of my father's work on "Obstetric Operations," I found the following: "We possess in ergot a great, a dangerous power of augmenting the force of the uterus. We want an agent endowed with the opposite effect, that will control and suppress uterine action. I consulted Dr. Richardson on this point. He tells me the desired power exists in the nitrite of amyl. Three minims of this added to one drachm of ether taken by inhalation is the form he recommends. It does not produce unconsciousness; but it is an anæsthetic as well as a sedative of muscular action. It is the antidote or opposite force to ergot. In it we have the desired 'epechontocic agent.'" In the case in question, the drug certainly acted admirably. It relaxed the irregular contraction of the uterus, and acted as a sedative and anæsthetic without producing unconsciousness. The case is also instructive as an example of the danger which may result from the administration of ergot before the expulsion of the placenta. The tetanic action was no doubt increased by the traction which had been made on the cord. It is well known that ergot, when given before the birth of the child, may cause its death. I believe this results from the blood being squeezed out of the placenta by the uterus. Although in cases of irregular contraction of the uterus that organ is firmly contracted, the contraction does not separate the placenta. On the contrary, in the cases I have seen, the placenta has been firmly adherent, as it was in this case. I am not aware that nitrite of amyl has been used to relax uterine spasm before. In it we possess, I think, a new and trustworthy addition to the resources at command for overcoming spasmodic or trismic contractions, which will not always yield to other remedies.

Septic Endocarditis.

The *Lancet* says that Professor Leyden, writing on this interesting subject in the *Zeitschrift für Klinische Medicin*, draws attention to the frequent resemblance of the temperature curve in this disease to that of intermittent fever, a resemblance that has been many times noted by others. He distinguishes, clinically, four groups of cases, as follows: The first group includes those cases in which the endocarditis forms part of a pyæmic or septic process. This is best known in connection with puerperal septicæmia, in which ulcerative (infectious parasitic) endocarditis is not infrequent. It is also sometimes met with in septicæmia and phlebitis following injuries. Leyden observed one such case complicated with abscess of the liver. In these cases of endocarditis, pyæmic or septic *par excellence*, the cardiac condition is part of a widespread septic process, and the rigors occurring in the disease may be symptomatic of the general sepsis, quite as much as of the endocarditis. In his second group he places those cases of endocarditis which are marked by a more or less intense and irregular pyrexia and erratic rigors. Traube has recorded such cases, so has Ditten. Volmer relates one in which typhoid symptoms ushered in the attack; then rigors occurred, and the diagnosis of endocarditis was made. Leyden remembers one such case in Traube's clinic, where a correct diagnosis of pulmonary valvular insufficiency was made, the endocarditis being accompanied by an irregular intermitting fever. The third and fourth groups comprise cases in which the temperature-curve corresponds, more or less closely, to that of intermittent fever, with periods of paroxysmal exacerbation, alternating with apyrexia, sometimes for a short period, regularly quotidian and tertian in type. In the third group he places those cases in which the signs of car-

diac disease are ill-marked, or even in abeyance until near the close of life; while in the fourth he describes those cases where heart disease has been long established, the intermitting fever arising as a final complication. He gives details of four such cases, and ascribes the issue to the supervention of some septic influence, sometimes ascertainable, and confirmed after death by the presence of mycotic organisms in the vegetations, and secondary emboli. It may be added as an interesting historical fact that Leyden states that he has been unable to find records of these types of fatal endocarditis among older writers. This we believe is quite true, and in the face of the very striking clinical manifestations, is a little remarkable, and not wholly to be explained by the absence of thermometric observations. It is more than likely that some cases known to our forefathers as malignant ague really belonged to this class of disease, although even Morgagni, who faithfully describes post-mortem appearances in association with clinical facts, gives no case that would now bear this interpretation.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Noblest Science—Annual Address at McKendree College, Lebanon, Ill., by Henry A. Castle.

——The Twenty-second Annual Announcement of the Bellevue Hospital Medical College has been received.

——We have received the Fifty-fourth Annual Announcement of the Medical College of the State of South Carolina.

——A Clinical Lecture on Idiocy and Imbecility, by Isaac N. Kerlin, M. D. This is a reprint from the Medical and Surgical Reporter.

——We have received the fourth biennial report of the State Board of Health of Maryland, a volume that reflects credit upon the energy and enterprise of the board.

——The annual commencement of the American Veterinary College of the University of the State of New York, No. 141 West 54th street, New York City, has been received.

——We have received the fifty-eighth annual announcement of the Jefferson Medical College of Philadelphia, which shows the institution to be in a most flourishing condition.

——We have received the report of the first commencement exercises of the Albany College of Pharmacy, containing the address delivered to the graduating class by Professor David Murray, PH. D., LL. D., as well as the second annual catalogue and announcement of the same institution.

——We have received the Biennial Report of the Board of Health of the Sandwich Islands, which contains much of interest, among other matters being an account of an official visit to the Leper settlement at Kalawao, Molokai.

——Refraction of the Eye, as distinguished from accommodation and estimated as an equivalent, from the index of refraction, by H. Culbertson, M.D., Assistant Surgeon, U. S. A., retired. This paper comes to us as a reprint from the Cincinnati *Lancet and Clinic*, May 27th, 1882.

——"Contributions to the Physiology and Pathology of the Nervous System." Part iv. From the private physiological laboratory of Isaac Ott, M.D. This pamphlet contains articles on the following subjects: The Physiology of the Spinal Cord; the Physiological Action of Glycerine; the Physiological Action of Hyoscyamia; the Cilio-spinal Centres; the Action of an Irritant.

——Papers and proceedings of the National Association for the Protection of the Insane and the Prevention of Insanity, at the stated meeting held in New York City, January 20th, 1882. This pamphlet, published by G. P. Putnam's Sons, New York City, is well worthy of perusal by all physicians, philanthropists, and all public spirited citizens, since it deals with one of the most perplexing social problems of the day.

BOOK NOTICES.

Clinical Lectures on Diseases of the Urinary Organs. By Sir Henry Thompson, Surgeon Extraordinary to His Majesty the King of the Belgians, etc. Sixth London edition. Illustrated with 73 wood engravings. pp. 175. Philadelphia: P. Blakiston, Son & Co. 1882. Price 75 cents.

Sir Henry Thompson stands so preëminent in all that relates to diseases of the urinary organs that one never hears his name mentioned but his specialty comes prominently up into the mind. There is probably no man living in the world whose utterances and teachings in this particular branch of surgery are so well worth studying. His experience has been incalculably great and extensive. Every physician must know something about the morbid conditions of these important organs, and he cannot do better than to learn from the well-stocked mind of Sir Henry Thompson. By using less expensive paper and binding the book in paper, the publishers have been enabled to offer all this valuable material at a very low price.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,

115 South Seventh Street,

PHILADELPHIA, PA.

THE DUTY OF RAILROADS TO PROVIDE AGAINST ACCIDENTS.

The sad accident which recently occurred near Long Branch, by the separation of the rails, and the falling of the train into a shallow river, was attended by scenes which again illustrated the necessity of railroads forming a regular staff of surgeons, and providing them with the means of attending immediately to fractures and similar injuries.

Every road should have a set of splints, bandages, lint, chloroform, and other materials required in the first attention to wounds, placed in charge of the station agent, at every important station. A surgeon-in chief and division surgeons should be appointed, prepared to come on any emergency, and some of the employees of the road should be instructed in the principles of ambulance duties, as of lifting and carrying wounded men, applying bandages, etc.

Even where an accident occurs close to a great city these precautions would be wise, and on the long lines which traverse the less thickly settled portions of our country, their observance should be enforced by law.

DR. JOHN L. ATLEE.

The venerable and celebrated Pennsylvania physician, who has just been honored by a unanimous election as President of the American Medical Association, is a *man* among men, a true scholar, gentleman, physician.

Dr. JOHN LIGHT ATLEE was born in Lancaster, Pa., November 2d, 1799. His father was Col. WILLIAM PITT ATLEE, and his grandfather the Hon. WILLIAM AUGUSTUS ATLEE. He studied medicine with SAMUEL HUMES, M. D., commencing in 1815, and graduated from the University of Pennsylvania in April, 1820. He then began practice in Lancaster, where he yet remains. He was active in the organization of the Lancaster City and County Medical Societies, and was twice elected president. He was one of the originators of the State Medical Society, in 1848; in 1857 he was elected president, and was elected one of the vice-presidents of the American Medical Association in 1868. At the union of Franklin and Marshall Colleges he became Professor of Anatomy and Physiology, and so continued until 1869. He has always taken a lively interest in the cause of education, and having been appointed a school director in 1822, he was for more than forty years an active and useful member of the board. He is a Trustee of Franklin and Marshall College, as well as of the Bishop Bowman Church Home, of Lancaster. He has been a contributor to the *American Journal of the Medical Sciences*, as well as to many others. He revived the operation of ovariotomy in 1843, and was the first to successfully remove both ovaries at one operation. He was married, March 12th, 1822, to SARAH H., eldest daughter of the late Hon. WALTER FRANKLIN, President Judge of the Courts of Lancaster and York Counties. He has two sons physicians, one of them the well-known ovariotomist, Dr. WALTER F. ATLEE, of Philadelphia. Dr. ATLEE's exceptional charac-

ter, long experience and well-known integrity eminently fit him for the position to which he has been elected.

Notes and Comments.

Spina Bifida Cured by Injections of Iodine.

Mr. A. Pearce Gould reported the following case to the Clinical Society of London (*British Medical Journal*): A boy, aged six months, was brought into the hospital, with a tumor over the lumbar vertebra about the size and shape of a large tomato. It was translucent, fluctuating, sessile, covered with healthy skin. The child was otherwise perfectly healthy. The tumor became tense when the child cried, and pressure on it caused fullness of the anterior fontanelle. One ounce of fluid was drawn off, and one drachm of Morton's iodo-glycerine solution injected. This producing no effect, the operation was repeated a week later, when half a drachm of the same solution was injected. After this the tumor became solid and shrank. The fluid removed was analyzed, and found not to contain even a trace of sugar, showing that it was arachnoid and not cerebro-spinal fluid. During the discussion that followed, it seemed to be the sense of the Society that while this was the best treatment known at present, for spina bifida, the successful cases were very few and far between. The President, in conclusion, stated that he believed that Dr. Morton now thought it advisable not to draw off the fluid from the spina bifida, but merely to inject the fluid, that being quite sufficient for the treatment of the case.

Prostatic Obstructions.

Dr. Reginald Harrison recently read a paper before the Medical Society of London, in which he advocated the wisdom of early treatment of prostatic obstruction. He believes that at least 33 per cent. of the men who pass 55 years of age, sooner or later, have enlargement of the prostate. He deprecated the idea of waiting until the prostate became so enlarged as to interfere with the passage of urine. He denied the generally taught idea that this gland is so very sensitive, and so resents mechanical interference; it will bear as much manipulation without resultant evil as any part of the body. He uses gum-elastic instruments, two to four inches longer in the stem than usual, with an expanded portion an inch from the tip, which is made to enter the bladder. Thus the prostatic urethra is subjected to stretching, both upon the introduction and the withdrawal of the instrument. If this dilatation is not carried out too rapidly, no irritation will ensue. He closed his remarks by urging, strongly, this early treatment, which, when properly and carefully carried out, will do much to prevent subsequent very serious trouble.

Epithelioma Removed by Scraping.

At a recent meeting of the Clinical Society of London (*Medical Times and Gazette*), Mr. T. Holmes related a case of a young man suffering from an ulcer of the leg, which presented all the appearances of epithelioma, both to the naked eye and under the microscope. It was very large, almost isolating the tendo-achillis, and was accompanied by the swelling of the inguinal glands. Mr. Holmes considered that in former times these symptoms would have been considered to warrant amputation. In this case he removed all the epitheliomatous tissue, and then made a free application of the actual cautery. Sound cicatrization ensued and the enlarged glands subsided entirely. Many other gentlemen related their experience in this matter, which was all corroborative of Mr. Holmes', who closed by saying, he suspected that many growths originally local tended to become epitheliomatous and constitutional in type. His case certainly corresponded to the ordinary descriptions of epithelioma, and he would urge that such cases, if early treated, might result in the extirpation of a disease rapidly becoming malignant.

Neuralgia.

Dr. Reginald G. Alexander, writing in the *Lancet*, makes the statement that it is now a well established fact that neuralgia is a disease arising from debility, and since it is very often mistaken for rheumatism, gout, spinal irritation, etc., he gives the following diagnostic points by which it can be differentiated: 1. Neuralgia occurs when general debility exists, is increased by fatigue, mental or bodily, but is relieved by food, and sometimes by stimulants. 2. The pain, which is sudden, darting and excruciating, exhibits remarkable intermissions, especially in the early stages of the complaint, and the constitutional disturbance is slight (temp., pulse, etc., frequently normal). 3. It is usually unilateral. 4. As the disease advances, tender spots are formed in the course of the affected nerves.

Realizing that debility plays so important a part in this disease, he says, as would be supposed, that the treatment must be directed in every case toward improving the general health. Pure air night and day, great cleanliness and sponging with sea salt and water. Hypodermic injections of morphia give immediate relief and are really curative, since by allaying pain they allow the tonic measures to be carried out.

Diet in Asthma and Bronchitis.

Dr. John C. Thorowgood calls attention, in the *Medical Press and Circular*, to the importance of carefully regulating the diet in cases of asthma and bronchitis. He describes how an overly distended stomach, by pressing on the diaphragm, may offer a mechanical impediment to free respiration, and may also interfere with the proper action of the heart. He mentions a gentleman who gained a great reputation for his ability to cure bronchitis and bronchial asthma by diet, and says that the great secret of this diet cure was judiciously starving the patient for a time. The stomach may be, to a certain extent, sluggish, so that it will not at the time feel any inconvenience from the excess of food forced upon it, but in an hour or two dyspepsia in some form will indicate the outrage that has been perpetrated. The food used should be nutritious, without being bulky. A lightly boiled egg, the wing of a chicken, or some fish, with one cup of tea, coffee or cocoa, and toast, will form three alternatives of breakfast fare. Soups should be avoided at dinner, because they tend to distend the stomach. Vegetables should be used sparingly. Malt liquors, pastry, cheese and dessert should be rigidly eschewed, and for drink, claret, with water, or lemon juice and water, may be allowed. Effervescing drinks of all kinds are not to be commended. By this arrangement of diet we keep up nutrition, while we avoid overloading the stomach, and so oppressing the diaphragm. The heart and lungs are enabled to act freely, and the danger of sudden stoppage of the first named organ is put at a distance.

Hereditary and Non-Hereditary Phthisis.

Dr. Reginald E. Thompson, in the course of a lecture on this subject, says (*Lancet*) that after examining a very large number of cases he finds the proportion of hereditary to non-hereditary cases to be 36 per cent., or, he says, the relative number may be roughly put as one hereditary to two non-hereditary.

The following numbers represent the relative proportions in which the several members of the families were implicated in the disease:—

Father alone	168	
Ditto, with one or more brothers	34	252
Ditto, with brothers and sisters	50	
Mother alone	158	
Ditto, with one or more brothers	25	241
Ditto, with brothers and sisters	58	
Father and mother	40	
Ditto, with one or more brothers	8	68
Ditto, with brothers and sisters	20	
Uncle	47	
Aunt	37	
Grandfather	7	439
Grandmother	5	
Sisters, with one or more brothers	152	
Brothers only	191	
Total		1000

Self-Mutilation.

Dr. Thomas Partridge thus writes to the *British Medical Journal*:—

At the present time, when the subject of self-mutilation is of so much interest, the following case may be worth notice, not, perhaps, from a medico-legal point of view, as the one recently under public notice, but as showing that some persons will inflict severe pain and injure themselves, at the risk of their own lives, from various motives.

Several years ago, when assistant-surgeon in a foreign naval service, my ship was stationed for three weeks in an extreme northern port of America. During our stay, several men contracted syphilis from the half-breeds (Indian and French). Three weeks or a month afterwards, when we had returned to our depôt, I was summoned to the surgical room to see a stoker, said to be dying. On arrival, I found him pallid, with a weak pulse, and very exhausted. On removal to the sick bay, I noticed a discoloration of the trousers about the thighs; and, on examination, detected bleeding from the penis. On retracting the prepuce, a jet of red blood spurted out. Calling in the assistance of my chief, we succeeded in stopping the hemorrhage by pressure and styptics, but, as may be imagined, not without some trouble. It transpired that the poor fellow, an Irishman, of low mental type, had a chancre. He thought to get rid of it by incision, and in doing so, wounded the dorsalis penis artery. The pocket-knife with which he cut himself was in his pocket, one blade having a smear of blood on it. Had a little longer time elapsed before he was noticed, death would have ensued, perhaps leading to various sur-

mises; and as he was disliked by his mates, this might possibly have caused unjust suspicions against one or other of them.

The Growth of Bacteria.

In the *Medical Press and Circular*, Dr. David Goyder says that a blood heat is most favorable for the growth of bacteria. Cold to the freezing point does not kill, nor heat to 250° F. destroy the life of spores, but both arrest their development. Compressed air and oxygen at first increase, but ultimately destroy spores and bacteria, and prevent development. Ozone at once destroys them. Pure hydrogen at first excites and then kills. Carbonic acid paralyzes but does not prevent their resuscitation by oxygen. Boracic acid kills them, and carbolic acid to $\frac{1}{20}$ per cent. prevents all development. Cohn has calculated that a single bacterial rod, by growth and division, will produce in two days of forty-eight hours the enormous number of 281,500,000,000, and at the same rate of development it would fill the ocean in five days; but, of course, other telluric influences prevent this.

Special Reports.

Mo. VI.—MICRO-GERMS.

BY DR. W. F. MUHLENBERG,
Of Reading, Pa.

(*Concluded from Vol.* XLVI, *p.* 615.)

In judging of the character of diseases produced by inoculation with the so-called specific germs, we must be thoroughly convinced that the disease produced is the one suspected, and not septicæmia or a local tuberculosis.* Animals must be proved to be able to take a certain disease, which resembles in its symptomatology that affecting man, and everything tending to interfere with or obscure a precise diagnosis must be excluded. Animals vary much more in their temperatures than man, and the effect of slight injuries, or even fright (particularly in rabbits) is very marked.†

If an organism be generated successively, in any medium, for a long period, it must become habituated to it; and, on its transference to another medium will require time to re-habituate itself. Its virulence may be interrupted by cultivation in the body (inoculation).

The supposed conversion of bacilli may be due to the fact that, as two media are ordinarily used, in the first the one organism was too subordinate to be noticed, whereas the second medium, suiting its necessities much better, may cause it to grow so vigorously as to crowd out and displace the bacillus predominant in the first medium. Pasteur's solution becomes milky, Cohn's moderately cloudy, and fresh urine slightly tinged, while a 2 per cent. solution of carbolic acid shows no effect, if, under like conditions, one drop of putrid fluid be added to each. The bacillus subtilis grows in its original medium to double its length, without changing its diameter; and then breaks into two rods, but, on the addition of sugar or serum to the fluid, forms filaments, instead of dividing. The development of germs appears to depend on the fluid and mode of culture used (31). In one case no permanent spores are found, in another no zooglœa mass. The micrococcus prodigiosus, grown on potatoes, is crowded out by bacterium, like the bacterium termo. Blue cocci, cultivated in Pasteur's solution, become colorless, but on admixture with pus, become blue, while, planted on potatoes, become red.

Septicæmia in mice (28) is always produced by the smallest drop of a culture fluid containing the micrococci, while in rabbits they produce an erysipelatous gangrene of the ear, with colonies of rosary-like micrococci, which can be cultivated in field mice, although they are insusceptible to the bacillus anthracis. Klebs, (32) one of the great authorities on mycology, considers the bacillus anthracis the cause of Charbon, and the bacillus malariæ, bacillus typhi exanthematici, and the bacillus typhi abdominalis,* the best examples of so-called

* Tuberculosis is now generally considered to be inoculable in animals; even in the shape of phthisical pus (30), and perhaps, as Rindfleisch suggests, the reason why many previous attempts at inoculation have failed, is because we are all hereditarily habituated more or less to the poison; but, even if micrococci are the vehicles of transportation, it is possible for them to be carried off by the blood sufficiently rapidly to do no harm.

† In the septicæmia of rabbits, immediately after inoculation, there is a rise of temperature of 2°-3° C., while, before death, it falls below the normal standard. There is also loss of appetite, debility, diffuse cellulitis, and occasionally a purulent collection near the puncture, while the subcutaneous connective tissue is full of bloody serum and micrococci. In judging of the bacillus malariæ, three factors were considered necessary to prove intermittent fever in rabbits.

1st. Distinct, intermittent feverish attacks.

2d. Enlargement of the spleen, firm, but not soft, as in septic spleen.

3d. Absence of marked diminution of the animal's weight, and the existence of black pigment in the spleen, blood and marrow (due probably to a liberation of iron from the hæmoglobin), as well as, *post-mortem*, absence of pus.

* The bacillus typhi (33) is found mainly in the enlarged lymphatics and spleen, while the bacillus of tubercular inflammation is found in the intestines. This same bacillus (34) has been found in drinking water, and appears to produce the same disease in rabbits.

specific germs, and views them as pathognomonic. While all acute abscesses (25) are full of micrococci, none are found in cold abscesses. There is only a serous discharge, where no micrococci are present in wounds. Pathogenic bacteria must enter the system in certain numbers to survive, or become virulent, for, if (35) the vitality of a rabbit is lowered by the administration of phosphorus, micrococci, which under other circumstances, do no harm, increase so rapidly as to be fatal. It is believed, (36) that a septic nephritis is frequently produced by the direct entrance of micrococci into the kidneys.

In the neighborhood where these colonies of micrococci are found, a virulent inflammatory action can be observed, while the signs of a diffused nephritis are present in the parenchyma. The micrococci act as emboli, and are found in the small intertubular arteries. Different facts, lately determined, render it probable that germs can traverse the glomeruli of the kidneys. The filtration of fat (37), and of bacilli anthracis (38), from the blood has been almost conclusively established; and, in addition, it has been shown (39) that the urine of healthy persons, if the access of air is prevented, contains no germs nor bacteria, remains acid, and does not undergo decomposition; while, on the other hand, (40) in infectious diseases, like scarlatina and typhoid fever, they are often found in great quantities in the urine.* In places robbed of their epithelium, (14) micrococci quickly enter the lymphatics and blood vessels, and are found in contact with the blood, pus, and plasma-cells, and (as is seen after injection of cinnabar) appear to enter bodily into them, destroy the membrane, and are excreted by the kidneys, or deposited on some mucous surface. Invading the body as they do, they either undergo the usual harmless transformation and perish, or, by some accident favoring their growth, like the effect of various culture fluids upon them, more readily transmit their species, and, when produced in immense quantities, by robbing the tissue underlying them, or some element necessary to their existence, bring on various disorders.

The fact of the presence of germs in various parts of the body, and various excretions and secretions, furnishes as yet no reliable criterion of their previous action on the organism. The question that always presents itself is, whether we can recognize with certainty, from these residual organisms, the prior existence of some definite disease. It has been found that in frogs, dying of septicæmia (Wassilieff, Strasburg Institute) a development of germs takes place *post-mortem*; while, in frogs not dying of septicæmia, none can be discovered, *ante, aut post-mortem*; yet sections of cadavers of dogs (Billroth *l. c.*) made immediately after death, and plunged into mercury or paraffin, have always been found full of germs. Saliva (43) injected into rabbits has produced septicæmia, but, on cultivation, it has been found due to germs. One general view seems to prevail, that septic affections arise without the presence of germs, and are produced by a substance formed by putrefaction, to which poisonous properties are ascribed. This view appears to be supported by the fact that, frequently, no considerable quantity of germs are found in the organism; but is untenable, because, as in relapsing and malarial fevers, they may disappear temporarily; and rarely all the fluids or organs of the body are examined; and by filtering such a septic fluid we can inoculate it with perfect safety. Whereas the separated germs, cultivated even to the thirtieth or sixtieth generation in harmless fluids, and representing only a billionth part of any chemical or bioplastic series, always produce disease. The apparent conversions of harmless germs into virulent ones, proves also there is no chemical poison. Many authorities say surgical injuries of various kinds, without external lesions, have had as a consequence septicæmia, and that although germs have been found in the purulent or muco-purulent secretions, they are either a post-mortem change, or a part of a process not injurious to the system. Some experiments appear to prove that the germs admitted to be omnipresent in the body, perhaps, after such accidents, find a nidus for their increase and peculiar action in the disorganized tissues. Ordinarily (44) after the subcutaneous castration of rams, a simple withering or calcification of the testicle ensues, but if, before castration, an injection of a germ-containing fluid is made into the blood, gangrene of the testicle is invariably produced, except when all the vessels leading to the testicle have been ligated. The

*Some interesting (41) cases of nephritic mycoses have been recently described, in which, post-mortem, were found tube-casts of a particular variety, so called germ-casts (Pilz-cylinder).

The tubes were found robbed of their epithelium, and colonies of micrococci were seen blocking up the tubules. These casts appeared to consist of a homogeneous vitreous basal-membrane, covered with micrococci. They were not produced by septicæmia, nor by ascent from the bladder. The symptoms of the disease were those of meningitis, but post-mortem, no lesions were found in the brain.

An acute nephritis (19) is often present with inflammatory affections of the tonsil, in which micrococci are found in great quantities in the urine. As one author says (42), it is not difficult to conceive that a mycelium-like growth of beaded-filaments, like micrococci, might act destructively on the lining membrane of the urinary passages.

germs in the blood, consequently, seem to be few, and not to increase without some stimulus. In the mouth are found, normally, the leptothrix pussilla, the leptothrix buccalis, the spirochæte dentium, the penecillium microsporinum, and a micrococcus which is colored blue by iodine. Normally (45) in the intestinal contents are found, micrococci, the bacterium termo, the bacillus subtilis, and saccharo mycetes, all stained yellow or brown by iodine, and the clestridium butyricum (Pasteur's vibrion butyrique) and a smaller variety, stained blue by iodine.

Iodoform (46), used now so largely as an antiseptic, exercises a constant antagonizing influence upon the germination of bacteria, and, if used in quantity, prevents the origin of putrefactive processes.

Sunlight seems to have some slight effect upon the growth of germs, as turbidity (47) did not take place in culture tubes exposed to its influence until the third day, whereas, ordinarily, it was noticeable on the first day. The following table gives the antiseptic as well as aseptic action of various bodies on cultivated flesh-extract solutions (48) :—

Aseptic.		*Antiseptic.*
1 : 25250	Corrosive sublimate,	1 : 5805
1 : 30208	Chlorine,	1 : 22768
1 : 11135	Hypochlorite of calcium,	1 : 3720
1 : 6448	Sulphurous acid,	1 : 2009
1 : 6308	Bromine,	1 : 2550
1 : 5704	Sulphuric acid,	1 : 2020
1 : 5020	Iodine,	1 : 1548
1 : 4268	Acetate of alumina,	1 : 427
1 : 3353	Oil of mustard,	1 : 591
1 : 2867	Benzoic acid,	1 : 410
1 : 2860	Borosalicylate of soda,	1 : 72
1 : 2005	Picric acid,	1 : 1001
1 : 1340	Thymol,	1 : 109
1 : 1003	Salicylic acid,	1 : 60
1 : 1001	Permanganate of potash,	1 : 150
1 : 669	Carbolic acid,	1 : 22
1 : 60	Chloroform,	1 : 112
1 : 62	Borax,	1 : 48
1 : 21	Alcohol,	1 : 4
1 : 14	Eucalyptol,	1 : 116

The following table, by another investigator, shows the antiseptic action of various bodies on the germination of bacteria (49) :—

Corrosive sublimate	1 : 20000
Thymol	1 : 2000
Sodium benzoate	1 : 2000
Creasote	1 : 1000
Ol. thym	1 : 1000
Oil of caraway	1 : 1000
Benzoic acid	1 : 1000
Methyl salicylic acid	1 : 1000
Salicylic acid	1 : 666
Carbolic acid	1 : 200
Quinia	1 : 200
Sulphuric acid	1 : 150
Boracic acid	1 : 133
Sulphate of copper	1 : 133
Hydrochloric acid	1 : 75
Sulphate of zinc	1 : 50
Alcohol	1 : 50
Chlorine	1 : 25000
Iodine	1 : 5000
Bromine	1 : 3333
Sulphurous acid	1 : 666
Benzoic acid	1 : 250

(Chlorine, Iodine, Bromine, Sulphurous acid, Benzoic acid: In the molten liquid.)

Dr. Sternberg (50), finding that the injection of some blood or serum from the subcutaneous connective tissue of a rabbit, killed by septicæmia, invariably produced death in rabbits in from twenty-four to forty-eight hours, thinks it is manifest that a negative result, after treatment with a disinfectant, is proof of its power to destroy the potentiality of the injected material. He finds that chlorine, nitrous acid and sulphurous acid gases are reliable disinfectants, in the proportion of one volume to one hundred volumes of air; and that the following bodies, added to one hundred parts of such a fluid, act as preventives :—

Iodine	.2	Salicylic acid	1.25
Chromic acid	.1	Zinc chloride	2.5
Ferric sulphate	.12	Caustic potash	1.
Cupric sulphate	.25	Iron alum	1.
Thymol, in alcohol	.25	Zinc sulphate	1.25
Caustic soda	.25	Potass. sulphuret.	2.
Nitric acid	.25	Tannic acid	1.
Sulphuric acid	.5	Boracic acid	2.
Iron sesq. chloride	.5	Potass. permang.	2.
Sodium hyposulph	.5	Borax	2 5
Hydrochloric acid	.5	Glycerine	12.5
Carbolic acid*	1.25	Alcohol, 95 p.c.	25.

Onimus (52) found that alcohol, iodine and sulphuric acid rendered septicæmic blood harmless, but neither quinia nor 45° C. were of any avail.

Davaine (53) found that $\frac{1}{10000}$ of a drop of blood from splenic fever cases, on inoculation, caused splenic fever, but that this was nullified by heating it to 55° C. for five minutes; and that, after the addition of one part of chromic acid to 7000 parts of diluted splenic fever blood, the animal died, while 1 : 5000 parts was sufficient to save its life. His experiments showed that animals died or survived by the use of the following proportions of antiseptics :—

Killed.	*Substance.*	*Saved.*
1 : 5000	Hydrochloric acid,	1 : 3000
1 : 300	Ammonia,	1 : 150
1 : 200	Silicate of soda,	1 : 150
1 : 500	Caustic potash,	1 : 375
1 : 200	Wine vinegar,	1 : 150
1 : 2000	Permang. of potash,	1 : 1250
1 : 8000	Sulphuric acid,	1 : 5000

And subsequently (54), when he mixed one part of splenic fever blood with 1000 parts of

* It requires the one-twentieth part of carbolic acid to prevent the growth of germs in beef extract (51).

water, and then one part of this mixture with ten of alcohol, he found it harmless.

Hatton (55) proved that phenol, alcohol and permanganate of potash were destructive to germs; and also cyanogen, until decomposed into oxalate of ammonia. While one hour's exposure (56) to dry heat, at 60° C., kills the bacteria of putrefaction, 20° C. does not, and it requires 75° C. (57) to kill the micrococcus prodigiosus.

Water in excess is sufficient to prevent the rapid growth of germs; but the most interesting fact is that the most powerful antiseptics and aseptics known are those chemical bodies produced by the disorganization of the germs themselves. The fact that carbolic acid, one of the reliable antiseptics, is the product of their decomposition, shows that we know, as yet, very little about their life, history, or the proper modes of developing or preventing their growth. Wernich (4) gives the antiseptic action of these aromatic bodies, as shown by the hindrance of the development of bacteria in 100 gm. of Pasteur's fluid, as follows: Skatol .05, phenylpropionic acid .1, indol 1, cresol .2, phenylacetic acid .25, phenol .5.

The diversity of action of antiseptics as deduced by different authorities, is undoubtedly due to the fact that various germs were experimented with, and that, in some cases, the bacteria, more readily antagonized, took the place of permanent spores. En résumé.

The bacteria of decomposition (58) appear to be the active agents in what is known as blood-poisoning, as has been shown by the investigations of Lister and Koch. It is affirmed that (59) "the micrococci of diphtheria may act upon the exudation of the trachea as the yeast plant acts upon sugar, and cause the production of a septic poison, which differs from that of ordinary putrefaction, and when absorbed, bears such relations to the system as to cause diphtheria;" and that (8) "they do not differ, as far as observed, from the micrococci of furred tongue, except in their tendency to grow in culture fluids; while their rapidity of growth is in direct proportion to the malignancy of the case." Dr. Sternberg (60), our great authority in this country, after advancing some valid reasons to show that as yet the proof of malaria being caused by the bacillus malariæ (Klebs and Tommasi-Crudeli) is unsatisfactory, says: "While, however, the evidence is not satisfactory, there is nothing in my researches to indicate that the so-called bacillus malariæ, or some other of the micro-organisms associated with it, is not the active agent in the causation of malarial fever in man; on the other hand, there are many circumstances in favor of the hypothesis that the etiology of this fever is connected, directly or indirectly, with the presence of these organisms or their germs in the air and water of malarial localities." Many authorities maintain that the micrococci of septicæmia are only the carriers of a poison, capable of producing the disease, and among them, Billroth (*l. c.*); "are only injections, after they themselves have been injected."

Others assume that the micrococci give rise to a chemical poison, which acts as a necrotic to the tissues, and which may be eventually obtained from the germs themselves, while others think there is a direct perforation of the tissues by the germs, and that they can wander into the blood corpuscles (Klebs and Hueter); others think that the bacteria, ordinarily present acquire power to change their locality, or mode of development. * It is believed (22) that during inflammation, processes arise in the tissues, which increase their resisting power to the germs, and, in many cases, prevent the natural modes of cure of infectious diseases. It is manifest (62) that the human body is used, in many places, as a nutrient substance by these organisms. The dependence of these organisms on the culture-media used, and the fact that micro-organisms, after cultivation, can be transplanted from one animal to another, while their life history is obscure, renders it probable that many diseases are caused by them.

The following diseases are common to men and animals (63): Glanders and farcy in horses; rabies in dogs and cats (also in skunks); anthrax in all domestic animals; tuberculosis in all animals; Asiatic cholora in all animals; milk sickness in cows; smallpox in chickens, pigeons. †

The germ diseases are also found in lower orders of animals, such as (65) the mucor-melitiphorus in bees (which are, as is well known, easily killed by yeast, a saccharomycete); petrine, flacherii and muscardine in silk-worms; the well known autumnal epidemic of house flies; and different varieties among fishes and birds. Pasteur believes that the germs of anthrax are conveyed to the surface of the earth, from the offal-

* Typhoid fever, *e. g.* in common with all intestinal mycoses, has the properties of making its cause affect the system, by its action on the intestinal canal. The bacteria found in the glandular apparatus are part of the metamorphosis of the bacillus subtilis, abundantly present in the large intestine. The organisms, living purely saprophytically in the colomi fæces, acquire the power to get into higher portions of the intestines, there accommodate themselves, and become invasive (61).

† Also in cattle, sheep, pigs, dogs, and apes, (64).

pits, by earthworms, but Koch has shown that they are very poor "messagers des germes." Our common insects, such as flies and mosquitoes, (Filaria-sickness), are now supposed to be carriers, as, contrary to the general opinion, the air is not crowded with germs as much as is supposed.

The portion of the system invaded seems to depend on the organisms, and, accordingly, various authors consider the respiratory tract (22), the intestinal tract (66), the tonsils (62), and skin as the favored localities of invasion.

These infectious matters appear to get in the air in dust form, more particularly as spores, but only after thorough drying.

Composed, as they are (67), of molecules of albumen and grape sugar, which ordinarily cannot be evaporated from a watery solution, it is hardly probable that ferments can be conveyed from any watery solution by currents of air.

The dried masses, or the residue of a dried fluid, transformed into dust by mechanical action of some kind, are subsequently wafted in all directions by currents of air. The presence of a gelatinous sort of material (especially in the case of the permanent spores) appears to cement the germs very firmly to the objects to which they were originally adherent.

It appears (68), from some experiments, that very strong currents of air cannot detach them from compact substances, as wood, iron and glass, while it requires only a weak current to free them from substances of an opposite or porous character, as cotton wool, silk, and the like. Currents of air, likewise, passing over or even through fluids, do not carry away with them any germs, unless the fluids become covered with foam. Some authors (67) even go so far as to say that moisture, and even dirt in houses, may assist in the purification of the atmosphere, by retaining the germs in contact with them.

In accordance with these facts, national hygiene would suggest (62) that no porous object, no bed nor mattress, should be cleansed in the bedroom. Wet cloths are best for removing dirt and germs from the walls and furniture. The safest means, also, for the removal of germs from the floor, or other surfaces to which they are adherent, is frequent and continued wiping of them with wet cloths; and with our present knowledge, it is far better to prevent the conveyance of a poison to the system than to neutralize it afterward.

Patients suffering from infectious diseases should have their own utensils, and not use a common water closet; not chiefly because the fæces may be a subsequent cause of infection, but to prevent the immediate deposit of germs on the rims of the seats. All vessels in use in a sick room should be washed out with a solution of at least five per cent. of carbolic acid. A plentiful stream of water through the water closets will carry away the germs; and the fæces can, with advantage, be buried or burned.

The urine should also be disinfected, and after sickness, all worthless matter burned, and valuable materials, where possible, disinfected by heat. Corrosive sublimate (and possibly calomel) is thought to be our most reliable internal antiseptic. Patients, where possible, should be washed with carbolic oil and water. What may be accomplished in future by a process of vaccination or attenuation of the hypothetical specific germs, is still problematical; but our present knowledge of germs warrants us in laboring in that direction, with the confident hope of securing some valuable humanitarian results. Single and very simple elementary principles in every department of science have led, through the persevering efforts of thoughtful individuals, to the most extended and beneficial consequences in human society. The telephone and electric light, in another department of pursuit, are now producing immense changes in the condition of society and the communication of thought; and the field of medicine is open in a similar way to reward the patient student of its mysteries with discoveries intimately connected with human happiness. As Franklin's simple experiment with the kite has led to the utilizing of the lightning of heaven for the benefit of humanity, so we may expect some future physician, by his labors, to make the very diseases of the human system contributory to their amelioration and cure.

Correspondence.

Inception of International Medical Congress of 1876.

Ed. Med. and Surg. Reporter:—

The enclosed copy of letter concerning the origin and purposes of the late International Medical Congress, which was assembled in Philadelphia, in 1876, may interest your readers, and furnish reflection and data to those who may, in future years, seek to promote an object of the kind.

Marshall, Va. Fred. Horner, M.D.

[*Copy*].

UNITED STATES CENTENNIAL BOARD OF FINANCE,
904 Walnut Street,
Philadelphia, June 13, 1873.

Frederick Horner, M.D., (*retired*) *Surgeon, United States Navy.*

Dear Sir: I am very much obliged by your letter of the 11th inst, giving me an account of the action taken lately at St. Louis, by the American Medical Association, on the subject of the great Centennial Celebration of 1876.

At your request, I now, in addition to the verbal communications I have had the pleasure of making to you, will state how I think the medical profession in the United States may contribute to the honor and success of the Centennial.

First, by causing to be prepared a full history of the data of medical science in the United States in the year 1776, and to trace the progress during the century, marking the great discoveries and improvements that have been made in it, the introduction of new remedies, the changes that have taken place in the treatment of diseases, the forms of surgical instruments then in use, and the changes therein that have brought them to the present forms. Next, the establishment of the institutions, universities, colleges, schools, etc., in the order, chronologically, of their establishment, their location, and brief notices of their growth and present condition. This, mainly literary work, might be amplified to any extent needed for the presentation of a complete history of medicine and surgery in the United States.

Secondly, by arranging with the U. S. Centennial Commission for space in the Exhibition building for an anatomical and pathological museum, in which might be displayed all such objects as could, with propriety, be presented for popular inspection, and to such a museum might be added private rooms for collections that would only be appropriate for special inspection and study by professional men and students. Such a museum should also contain full specimens of the surgical instruments, bandages, etc., used in old times, and others of the intermediate and progressive periods, finally presenting those in use now.

Thirdly, the coöperation of the medical profession is earnestly desired in aiding our plan, and through the instrumentality of the state, county and city medical societies, such coöperation may be readily and effectually had.

Respectfully yours,

Fred. Fraley, *Secretary.*

Salicylic Acid as a Remedy for Corns.

ED. MED. AND SURG. REPORTER:—

I wish to call the attention of our profession to Mr. Gezou's remedy for corns, which you published in your journal, July 17, 1880, p. 63. In the "Transactions of the Medical Society of Pennsylvania," for the year 1876, p. 283, I reported the use of salicylic acid in the treatment of corns. I used it first in the treatment of soft corns, but very soon found it would remove hard ones as well. I applied it on cotton, and I can testify to the certainty of the effects of salicylic acid in the treatment of these painful excrescences on the toes.

It occurred to me, when I read Mr. Gezou's prescription, that the collodion which he employed to dissolve the acid would keep it well applied to the corn, and I have used it as prepared by him, in a great many cases, since July, 1880, and I can say with constant success. I have had a preference expressed in favor of the application of the acid on cotton, but I have, in almost all of my cases, used Mr. Gezou's preparation since July, 1880.

The collodion, as already mentioned, fixes the acid on the diseased part, and gives speedy relief by protecting it from friction. The cannabis indica acts as an anodyne, and the acid reduces and loosens the corn, so that it comes off in four or five days, adhering to the collodion. The remedy is applied with a camel's hair pencil, and if the corn is not well cured, the application may be repeated. In four or five days the patient should use a warm foot-bath and rub off the collodion. If any portion of the corn remains the acid should be applied again, and the treatment continued until the whole of the corn has disappeared. The skin will be soft and smooth, as in the healthy state.

The mixture dries immediately, and does not prevent for a moment the use of the stocking.

I have used salicylic acid in the treatment of bunions with like good results.

Collodion as found in the shops makes a good mixture, but I have found Dr. Edward R. Squibb's flexible collodion preferable, as it makes, with the other ingredients of the remedy, a denser fluid. The extract of cannabis should be the solid extract.

I have written this communication because I thought the slight notice of the remedy in the REPORTER did not attract the attention of its readers. I am sure no remedy has ever been proposed which is so useful in those painful affections of the feet as salicylic acid. There are many diseases of the human body which seem to be trifling and do not receive that attention which is due from physicians and surgeons, though exceedingly annoying to their patients. I have been the recipient of the gratitude of many patients for the relief from suffering which this remedy has given them.

Let us do all we can to cure them. Mr. Gezou's formula, as given in the REPORTER is:—

℞.	Salicylic acid,	30 parts or grs. xxx
	Ext. cannabis indica,	5 parts or grs. v
	Collodion,	240 parts or f℥ ss.

NEWS AND MISCELLANY.

Massachusetts State Medical Society.

The one hundred and first annual meeting of the Massachusetts State Medical Society was in session in Boston, June 13th and 14th, 1882.

TUESDAY, JUNE 13.

The first paper, on "Cottage Hospitals," was read by Dr. L. W. Baker, of Baldwinsville. Small, detached, one-story buildings are more favorable, hygienically, for the treatment of patients than are the large, many-storied city hospitals. During the past twenty years the cottage hospitals of England have annually relieved some 50,000 patients. In that country it has been found that cheap wooden buildings provide the best accommodations for the sick. A cottage hospital, with capacity for at least twenty-five beds for children, can be erected, including land, for $5000.

Dr. J. W. Hannum, of Ludlow, followed with a paper on "Disease Germs," which was a review of the most recent discoveries in this branch of pathology.

Dr. Walter Ella then read a paper on the *Coincidence of Anal Fistula and Phthisis.* About twenty per cent. of patients suffering from fistula in ano are phthisical. The following are the reasons why, in his opinion, the phthisical have anal fistula so often: 1. Because of tubercular deposit in the rectal walls near the anus, with subsequent ulceration and fistula. 2. The retention in Morgagni's pockets of tuberculous diarrhœal discharges, subsequent inflammation, burrowing and fistula. 3. Inflammation starting in some of the numerous submucous rectal glands, which are prone, in tuberculous patients, to become inflamed, and abscess follow.

A paper on *Some Obscure Mental Symptoms of Disease* was then read by Dr. Charles F. Folsom.

AFTERNOON SESSION.

The question of the admission of women was brought up at this session, and again in the evening, at the Councillor's meeting, when it was indefinitely postponed.

WEDNESDAY, JUNE 14.

Dr. J. H. Robbins, of Hingham, presented a paper on *American Dyspepsia.* He believes that the great prevalence of dyspepsia in this country is the result of neurosal causes. He then went on to recite the various nervous conditions, such as worry, fright, anxiety, etc., that are known to produce dyspepsia.

A Study of the Action of Iron was the title of a paper read by Dr. C. H. Williams, of Boston. The results of experiments on animals inclines him to the belief that we have in iron, though not a dangerous element, yet a drug of more toxic qualities than is generally imagined. Iron should be given on a full stomach. The good following its use would seem to be due rather to its action in promoting digestion and assimilation than to the increase in the number of blood corpuscles, which is probably a result of the improved nutrition.

Dr. W. W. Gannett, of Boston, read the concluding paper of the session, and took for his subject *The Relation of Mould Fungi to Disease.*

The annual discourse was delivered by Dr. James P. Lynde, of Athol, on *Infantile Mortality*; *Its Causes and Prevention.* A vote of thanks was tendered Dr. Lynde.

OFFICERS FOR THE ENSUING YEAR.

President.—Alfred Hosmer, M.D., of Watertown.

Vice President.—J. H. Mackie, M.D., of New Bedford.

Treasurer.—Frank M. Draper, M.D., of Boston.

Corresponding Secretary.—C. W. Swan, M.D., of Boston.

Recording Secretary.—F. W. Goss, M.D., of Roxbury.

Librarian.—David H. Hayden, M.D., of Boston.

Orator for Anniversary in 1883.—Amos H. Johnson, M.D., of Salem.

Anniversary Chairman.—Francis H. Brown, M.D., of Boston.

The President introduced to the Society the President-elect, Dr. Alfred Hosmer, of Watertown.

The Society then adjourned to the Music Hall, where more than seven hundred Fellows dined and listened to after-dinner speeches.

The next annual meeting will he held in Boston, on the second Wednesday in June, 1883.

A Singular Case.

The Paris medical men, especially specialists in nervous diseases, are much interested, it not puzzled, by a patient recently received at the Beaujon Hospital. She was found by two policemen, insensible, on a seat in the Champs Elysées. At the station-house, Dr. Pinel was unable to restore her to consciousness, though he used every known means. She was in a state of ecstacy, her eyes wide open, and a smile on her lips. She remains mute; eats but little, and seldom. She is far advanced in pregnancy.

White Lead Factories.

We learn that the Gateshead (England) guardians have had their attention called to the condition of the employés of the white lead factories of the neighborhood. Decrepitude, palsy, blindness, and even death resulting from the lead poisoning. They will take steps to secure the introduction of machinery for the most injurious parts of the work. This is an example worthy of imitation in our own country.

Items.

—Sir Erasmus Wilson is improving very much in health.

—A Medical Students' Club has been organized in London.

—The next meeting of the Obstetrical Society of Philadelphia will be held September 7th.

—The meeting of the British Medical Association this month will celebrate the fiftieth anniversary of its foundation.

—Dr. J. S. Billings has accepted the invitation to deliver the annual oration before the Medical and Surgical Faculty of Maryland in April, 1883.

—Mr. Thomas Griffith, of St. Helena, Lancashire, England, who had been in practice there for twenty-one years, and who had been in the habit of taking chloral for the purpose of inducing sleep, accidentally took a larger dose than usual, with a fatal result.

—The eminent surgeon, Baron von Langenbeck, has tendered his resignation of the Professorship of Surgery in the University of Berlin, which he has held for many years with advantage to surgical science and honor to himself. His resignation has been accepted by the Prussian Government; and instructions have been given to take the necessary steps for the appointment of a successor, to enter upon the duties of the chair in October.

—A "Philanthropic Corps" has just been established by Herr von Madai, the President of the Berlin Police, composed of police officers and constables, a certain number of whom are chosen from the different police divisions. These members of the force are to attend weekly lectures at the Town Hall, on the treatment of invalids and sick persons suffering from sudden illness or accidents. It is expected that, shortly, about three hundred constables will, by these means, obtain sufficient knowledge of medical science to treat sufferers before regular medical aid can be procured. Attention will especially be directed to the best means of restoring life to persons taken from the water.

OBITUARY NOTICES.

Dr. William H. Studley, of New York, died of pneumonia, in that city, June 12th, ult. He was born in Bridgeport, Conn., February 21, 1827, graduated at Trinity College, Hartford, in 1850, studied in the Protestant Episcopal Divinity School there, was ordained by Bishop Brownell, but after two years' service in different parishes, owing to feeble health, determined upon a medical career. After a partial course at the Rush Medical College, Chicago, he received his degree from the College of Physicians and Surgeons, N. Y., in 1860. He was chiefly known as a contributor to some of the journals devoted to gynecology, and also as an inventor of some instruments of value. As a writer he was trenchant, lucid and original. As a debater he was always interesting.

QUERIES AND REPLIES.

J. W. C., in our issue of June 17th, is answered by a correspondent as follows: Give from five to eight drops of the tinct. iodine comp. in a wineglassful of water, three times daily, immediately after meals, uninterruptedly, during four weeks.

E. W. McG., Canada.—You can buy the articles you desire of any first-class drug store.

JOHN C. BAKER & Co., Philadelphia, Pa.

180-eowtf

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

Lecture.

CERTAIN ACCIDENTS OF BRIGHT'S DISEASE.

BY M. DIEULAFOY,
Prof. Agregé of the Faculté de Medécine de Paris.

Polyuria or Pollakiuria.

Gentlemen:—Among the troubles observed during the evolution of Bright's disease there is one to which I desire especially to call your attention; this is the frequently recurring desire to pass water, amounting in some cases to a veritable incontinence of urine. There are patients with chronic nephritis, who are obliged to urinate ten or twelve times during the night, thus inducing persistent insomnia. I have myself observed cases where the patient was obliged to pass water fifteen or twenty times daily, and two women in my service suffered from an almost constant desire to urinate.

But it must be understood that this frequent micturition is not due to the secretion of an exaggerated quantity of urine. There are certain diseases, glycosuria and diabetes insipidus, for instance, in which the patient urinates frequently, because there is a large secretion of urine; in certain cases of Bright's disease, also, the secretion is so exaggerated as to induce frequent micturition; but at present I intend to take into consideration only those cases where the frequent micturition is independent of the amount of urine secreted, sometimes coinciding with an abundant secretion, and at others accompanying a secretion which does not amount to a few hundred grams in the twenty-four hours.

There is, then, in Bright's disease, two distinct and independent urinary symptoms; the first, which I will not at present speak of, being a trouble of secretion, polyuria, and the second, which I will consider in this lecture, is characterized by the frequently recurring desire to pass water. Although these differing urinary troubles have been perfectly distinguished by contemporary authors, Jaccond (Traité de Pathologie Interne, vol. 2, page 417), Lecorché (Traité des Maladies des Reins, p. 387), and Rosensteim (Traité des Maladies des Reins), they are yet too often confounded together and considered under the designation polyuria, which is incorrect, as polyuria simply refers to a trouble of secretion. Frequent micturition constitutes, I repeat, an independent symptom, having its own special value and importance; it becomes, then, necessary to confer on it a special designation, and I propose the denomination pollakiuria (from $\pi o \lambda \lambda \alpha \chi \iota \sigma$, often). The term polyuria will then serve to designate an abundant secretion, while pollakiuria would signify a frequent call to urinate.

Brightic pollakiuria may come on very early or very late in the course of the disease, and in some cases is associated with pain. Precocious pollakiuria is that which accompanies the primary symptoms of Bright's disease; it is associated or not with epistaxis, cephalalgia, albuminuria, attacks of dyspnœa, polyuria, cramps in the muscles, œdema of the face and extremities, and troubles of sight and hearing; all symptoms which may appear singly or be associated together at any period of the evolution of the malady. Here is an example of pollakiuria appearing at the début of the disease:—

M. Y. complains of violent headache for the past two months; he has slight epistaxis just after rising in the morning. For the past few days he passes water very frequently, although the quantity of urine is not increased; he is obliged to rise four or five times during the night to evacuate the bladder. He recalls having had another such attack about two years since, with pollakiuria and slight epistaxis, so that his malady dates back two years, at least. Since that time he has been troubled from time to time with lumbar pains, which he considered an attack of lumbago, violent headache, slight troubles of audition, and attacks which he considered of asthmatic origin, but as these symptoms did not at any time last long and were not of great intensity, they gave him no great anxiety.

What troubles him most at present is the pollakiuria; there is no polyuria and the urine contains but five grains of albumen per quart.

In a few cases pollakiuria is an isolated symptom, appearing as the initial sign of commencing Bright's disease; nevertheless, careful examination will generally reveal other symptoms, not at all prominent, it is true, but which will permit us to affirm the existence of Bright's disease. In the following observation this species of pollakiuria was well marked: Mme. D., fifty-two years of age, complains, for the past six months, of very frequent calls to urinate, particularly during the night, passing each time but a small quantity of urine, for the entire amount passed during the twenty-four hours does not exceed forty ounces.

There is, then, pollakiuria without polyuria. The analysis of the urine gives but traces of albumen.

The symptom pollakiuria is so marked in this case that it appears as the unique and initial sign of commencing Bright's disease. But after careful questioning we find that she has had on several different occasions ringing in the ears, and that hearing is much enfeebled in the left ear. She has had slight epistaxis, cramps in the limbs, and frequently itchiness of the skin over the left arm and forearm. A slight bruit de galop is heard on auscultation of the heart.

The first analysis of the urine, made by M. Yvon showed exceedingly slight traces of albumen, six drachms of urea per quart, with a density of 1.020, the urine being slightly acid. A second analysis, made nine months later, gave three grains of albumen per quart, with four drachms of urea and a density of 1.019.

In other cases pollakiuria appears very late in the course of the disease.

Mme. G. had, in the course of December, 1879, a very grave attack of scarlatina, accompanied or complicated with nephritis and albuminuria. M. Weber, who had care of Mme. G. during the attack of scarlet fever at Amelie-les-Bains, several times examined the urine, and has kindly furnished me with the data of the case at that period.

After the first acute period, characterized by generalized anasarca, with albuminuria, attacks of dyspnœa, etc., Mme. G. experienced a notable amelioration, and for three months traveled on the continent, believing herself completely cured. But very soon after the acute period succeeds the insidious and latent course of the chronic disease. Arriving at Paris during the month of March, the patient commences to suffer from pollakiuria, and is obliged to rise twelve or fifteen times during the night to evacuate the bladder, which causes a veritable state of insomnia. The urinary secretion is below the normal average.

The patient complains of great pain in the left lumbar region, a creeping sensation (fourmillements), with numbness of the fingers, nausea and cephalalgia. There is slight localized œdema of the foot, the leg, and the left lumbar region.

Analysis of the urine shows a very acid reaction, a density of 1.028, with five drachms of urea per quart, and but slight traces of albumen. The milk diet is not well tolerated; she takes hardly a quart of milk per diem. The micturitions are very frequent, but the secretion of urine is so much below the normal that there is not a pint in all for the twenty-four hours.

Soon after very grave nervous symptoms supervened, the urinary secretion was entirely suppressed, and there was violent cephalalgia, accompanied with somnolence and torpor.

I will not insist on the other peculiarities of this case. I wished only to call your attention to the symptom pollakiuria, and demonstrate to you that it coincided, in this case, with a gradual fall in the quantity of urine secreted.

In certain cases, particularly among women, the pollakiura is painful. Two of the patients in my service have presented this peculiarity. The first, who succumbed through the progress of the disease, was, at the same time, affected with phthisis and Bright's disease; the autopsy revealed the lesions of mixed nephritis; the other is at present under observation. With both these patients pollakiuria was excessive; the calls to pass water recurred constantly, and this symptom was prominent from the beginning of the malady. The quantity of urine passed at each micturition was very small, at most a

teaspoonful, and each time pain followed, not at the moment of emission, but just afterward. This pain was very acute and had all the characters of a spasm; it was due, probably, to painful tenesmus of the neck of the bladder, a spasmodic condition of the sphincter muscle. The pain generally lasted several minutes, and reappeared after each micturition.

The few illustrations I have given suffice to prove that polyuria and pollakiuria are independent urinary troubles; polyuria is a trouble of secretion, the kidney being the organ affected, while the other, pollakiuria, is a trouble of excretion, due to vesical derangement. It is even remarkable that in Bright's disease the troubles of excretion often precede those due to disorders of secretion, and the frequent call to urinate may appear a long time before any exaggeration in the quantity of urine secreted.

Pollakiuria is due to exaggerated excitability of the vesical mucous membrane or of the muscular coats of the bladder. When the muscles of the body of the organ are affected, pollakiuria supervenes sooner or later, with more or less urgent calls to urinate; when the vesical sphincter is the cause of the frequency of micturition, the act is often followed by more or less prolonged and painful spasm.

As regards the cause of these troubles of the organs of excretion when the apparatus of secretion alone seems affected, it is impossible to form an opinion. Are these symptoms due to modifications in the composition of the urine itself I do not think so, for the symptom pollakiuria often supervenes at the début of the malady when examination of the urine reveals nothing abnormal. Can they be due to reflex action having origin in the kidney and affecting secondarily the bladder? This is possible, but there is no proof, and, in fact, the vesical symptoms often appear at a period when the renal lesions are as yet far from apparent.

For that matter, the indecision we feel in attempting to explain the vesical symptoms of Bright's disease is not at all surprising, for the same difficulty exists with other organs whether the symptoms affect the heart or the liver, or consist simply in œdema. But although the pathogenesis be yet far from elucidated, the clinical study is not the less interesting, and some elements to aid diagnosis may be drawn therefrom.

In effect, in presence of a patient suffering from pollakiuria and yet presenting none of the lesions which ordinarily give rise to frequent micturition, such as calculus, hypertrophy of the prostate gland and vesico-prostatic tuberculization (Guyon), we should consider the possible début of Bright's disease. And if the patient be then very carefully examined, certain other symptoms of the disease, perhaps but slightly marked, may be elucidated.

For a long time my attention has been devoted to the modes of evolution of Bright's disease. With the exception of a few cases where the origin and début of the malady are clearly indicated, as in scarlatina and certain cases of acute epithelial nephritis; with such exceptions it has seemed to me in a great number of cases of Bright's disease it is very difficult to fix precisely the period of development, and the pathogenesis is oftener still more obscure. In 1827, when Bright wrote his remarkable memoir, it required all his great talent of observation to create the morbid entity which bears his name.

This pathological entity was based clinically on the presence of œdema accompanied by coagulable urine. But these principal symptoms are often wanting and do not supervene until an advanced period of the malady. I have on several occasions been convinced that cases regarded as nephritis of sudden onset and very rapid course were, in reality, cases of nephritis of slow evolution, during the course of which an acute attack supervened. An individual consults us, stating that his health has been considered good up to within a few days or a few weeks. Now he suffers from lumbar pains, attacks of dyspnœa; his face is slightly puffed, there is some œdema of the feet, and the urine contains albumen in slight proportion.

At first this would appear to be a case of acute nephritis of a few weeks' duration; but if the patient be carefully interrogated as regards the state of his general health previous to this acute period, it will be found that he has suffered from frequent headache, that for the past two years he has had attacks of pollakiuria and cardiac palpitation. That from time to time he had slight epistaxis in the morning, ringing in the ears and diminution of hearing capacity, and other symptoms apparently of slight value, which will serve to show that the evolution of the malady has been going on for several years before the acute attack supervened. We do not, consequently, at present, wait for œdema and albuminuria to affirm the existence of Bright's disease.

Œdema appears very late in certain forms of nephritis, and albumen may be a long time wanting or disappear entirely from the urine at times. So that, in order to arrive at a correct

diagnosis when these two principal signs are wanting, the other symptoms should receive careful attention. In a doubtful case an abnormal heart sound (bruit de galop de Potain) removes all uncertainty as regards diagnosis. The auditory troubles of Bright's disease have not as yet received the attention they merit, but the ocular troubles have drawn considerable attention, and ophthalmoscopic examination may prove invaluable in a difficult case. I need not point out the value of early diagnosis, as therapeutic interference has most efficacy when commenced at an early period of the disease.

Communications.

REMARKS ON SOME OF THE DISEASES OF THE EYELIDS.

BY C. H. BROWN, M.D.,
Of Lancaster, Pa.

The eyelids may be considered as parts of the general integument, but as having undergone certain modifications to fit them for the purposes they are intended to subserve in the economy. In accordance with this view, the different affections of the lids are only repetitions of those diseased conditions which are constantly occurring elsewhere on the skin. And as these latter diseases, with some exceptions, are often successfully treated by the general practitioner, without referring them to a dermatologist, so, with the same reservations, may the diseases of the eyelids also be treated, and just as successfully, by the general physician; thus obviating the necessity of recourse to the oculist. This is a great advantage to the physician, not only because it enables him to pocket the fee which would otherwise go to the specialist, but because it is a great satisfaction to be able to cure these troublesome diseases, as many of them are, and it gives the physician so much better standing in the eyes of his patients and of the community.

But many physicians fall into the opposite error; instead of sending all their eye patients indiscriminately to an oculist, they attempt to treat all such diseases themselves, whether the trouble be simple or severe; and although some cases certainly recover under their treatment, many others have their sight irreparably damaged by unskillful treatment, and finally are compelled to seek a specialist's advice, only to find that it is too late. This is especially the case in affections of the cornea and iris; the patient applies to his family physician, who, after a superficial examination, sees that the eye is red and watery, and immediately prescribes an astringent wash. Now, while astringents are used with the happiest effect in the treatment of conjunctival affections, they are, on the other hand, highly productive of mischief when the cornea or iris is inflamed, and corneal and iritic diseases are thus stimulated to a state of severity that is seldom attained under other conditions. The physician, thinking the severity of the disease is due to an aggravated form, perseveres in the use of his nitrate of silver or some other equally astringent collyrium, or even increases the strength of it, until finally the eye succumbs to the combined assault of the disease and the remedy, and its usefulness is entirely destroyed, unless the patient, before this stage has been reached, in sheer despair, makes a change of physicians. In the case of iritis, the iris is bound down to the lens by extensive synechiæ, which condition is one of serious import; and in the case of keratitis, the cornea becomes perfectly cloudy and opaque.

It has fallen to my lot recently to see a number of such cases; the damage had been done, and in many of the cases I was unable to hold out any prospect of bettering the condition of their eyes. Although it was unpleasant to hear some of them denounce their physician, and in very emphatic terms, yet the question arises, are the physicians blameless?

In the May, 1881, number of the *American Specialist*, in an article headed, "The Consequences of Neglect in the Treatment of Eye Diseases," I related the history of several cases where the loss of sight was distinctly traceable to neglect and wrong treatment by the attending physician, and where, in all probability, the sight could have been saved by proper treatment.

It is selfish and unprofessional for a physician to treat every case of eye disease that comes under his care, whether he understands the nature of the diseased process or not, in view of the damage that is possible under improper treatment. It would be much safer for both physician and patient, safer for the physician's reputation, and safer for the patient's eyes, if all eye cases were immediately turned over to an oculist. But these are the extremes, and the judicious and conscientious physician may be able to strike a happy mean; to treat some cases with satisfaction to the patient, and credit to himself; and in other cases, with equal satisfaction and credit, refer the patients to a competent ophthalmologist.

These are important truths, and cannot be too often repeated, but the further consideration of this subject does not properly come within the

scope of this article, which is intended, simply, to refer to those diseases of the eyelids which the physician may safely and successfully treat.

Hordeolum—Stye.

One of the most frequent and unpleasant of the diseases of the eyelids (especially unpleasant if it occurs in one's own person), is a stye. Stellwag says ("Treatise on the Diseases of the Eye," by Dr. Carl Stellwag), "stye is a swelling of a tarsal gland, which is filled with a substance resembling pus, and occurring with inflammatory symptoms." Wells says (Treatise on the Diseases of the Eye," by J. Soelberg Wells), "this disease is not, as is sometimes supposed, an inflammatory affection of the meibomian glands, but is a furuncular inflammation of the connective tissue of the lids, having its seat, generally, in the vicinity of the hair follicles and near the margin of the lid." Which of these two authorities is correct, is not for me to decide, but for myself, I prefer to regard a stye, as Wells describes it, as a furuncular inflammation of the connective tissue of the lids.

Every one is familiar with the appearance of a stye. Beginning as an apparently harmless pimple, it soon develops a more or less angry inflammation, and passes through the ordinary stages of suppuration and discharge. In some cases there may be a good deal of feverishness and constitutional disturbance; but even if there is not, the patient feels disinclined to perform his ordinary duties, and can only use his eyes with considerable discomfort. The swelling, too, causes a good deal of disfigurement, and sometimes is sufficient to close the eye.

In the *treatment* of this troublesome affection, it is well to remember that a stye can seldom be "backed," that is, the disease seldom undergoes resolution; and the trial of various measures for the prevention of suppuration by the application of cold compresses, etc., is simply a loss of time and prolongation of the trouble. And, therefore, I consider the early application of hot poultices as *the* treatment. These poultices should be changed frequently, as often as every fifteen or twenty minutes, and thus the stye is hurried through its various stages, and often brought to a head in the course of ten or twelve hours. I usually order the ground flaxseed to be mixed with a dilute solution of sugar of lead, or have a few drops of the lead solution sprinkled over the poultice at each renewal, as the lead serves to allay the scattering inflammation and to concentrate it.

It is a mistake to pick at the stye with needles, to see if matter has formed; this, almost invariably, aggravates the trouble. The physician should wait until he is sure of the existence of pus, that is until the skin has become thinned and the apex of the swelling presents an unmistakably grayish-yellow tint; then a small incision should be made, to permit of the ready escape of the pus, and pressure should be made along the edge of the lid, toward the opening, so that the contents of the swelling may be thoroughly evacuated, and then in many cases the stye is practically well. After the incision, the inflammation always rapidly diminishes, the pain, which may have been quite severe, abates, and any further trouble from the hordeolum is scarcely to be feared, or perhaps the swelling may have opened spontaneously, in which case there remains nothing for the surgeon to do but to make the opening more complete and to fully evacuate the contents of the swelling by pressure.

Very frequently, however, a stye on the lower lid is followed by one on the upper lid, and the disease shows a great tendency to recur again and again, so that it would seem as though some individuals and some constitutions were especially liable to it. It is said to occur most frequently in persons of delicate health, and doubtless is an indication that one's system is below par.

It is in these cases that most authorities advise the use of tonics; but of all the remedies that have been recommended in this condition I think that lime is decidedly the best. It seems to have a specific influence over those cases of inflammation of cellular tissue which terminate in suppuration. Given a case in which boils are being continually developed, the use of lime will effect a radical cure. It may be given in the form of lime water, in doses of a wineglassful three or four times a day; or in the form of calcium sulphide, which is perhaps the preferable form, in doses from of $\frac{1}{10}$ to $\frac{1}{4}$ grain three or four times a day. In prescribing the sulphide I order the pills or granules in preference to powders or a solution of the remedy, as I find in the latter forms it deteriorates rapidly.

Blepharitis.

Perhaps the most important of the diseases of the eyelids, very common among hospital patients and the lower classes, is one which has received a great variety of names. It is an inflammation of the edges of the lids, and it has been called tinea tarsi, ophthalmi tarsi, blear eye, blepharitis marginalis or ciliaris, etc. Blepharitis is perhaps the term most often used, and it serves very well to express the nature of the disease.

In the mildest forms of the disease we notice only a reddened and slightly thickened condition

of the edges of the lids; there is at the same time a feeling of heat and itching in the eyes, which is aggravated by exposure to a bright light and by long continued use of the eyes on fine work. This is a condition that is quite common, and is found in connection with many eyes that are not considered weak, and whose owners never apply for treatment.

In a little more severe form of the disease we find the lids red and glazed, and perceptibly thickened. On awaking in the morning the patient finds that the lids are stuck together, and that small crusts have formed upon the lids and around the lashes, which are stuck together in little bundles by the hardening and drying of the discharge. The lashes become loose and fall out. For some time new lashes are formed, but are more likely to be stunted and crooked than of normal growth. If, however, the disease is severe or protracted, the lashes to a great extent cease to grow, and the lid presents but a few thin, straggling cilia sparsely scattered along its margin.

Marginal blepharitis seems especially apt to occur in persons of feeble health or of scrofulous constitution, and in such cases it proves very obstinate and prone to recur, even after an apparent cure. Indeed, some authorities consider this disease nothing more or less than an eczema attacking the margins of the lids. ("A Practical Treatise upon Eczema," by Dr. McCall Anderson, page 197.) Blepharitis is, in its nature, an essentially chronic disease, and may last for months and years. In some cases it is an habitual disease, sometimes better and sometimes worse. It seems scarcely necessary to give a further or fuller description of the disease, as it is usually easily recognized, and its appearance is familiar to most physicians.

In the *treatment* of blepharitis the greatest attention must be paid to cleanliness. In its early stages, before there is serious involvement of the hair follicles, and before the lids are distorted by the shrinkage of the inflammatory effusion, the disease is amenable to treatment. It is, however, very necessary to lay bare the seat of the disease by the complete removal of the crusts, and to apply the remedy to the diseased follicles with sufficient perseverance.

It is related of Sydney Smith that he once saw a little girl playing with a tortoise, and in order to please the animal, patting it on the back. He stopped to speak to the child, being amused at her futile efforts to make friends with the animal by patting its insensible shell, and explained to her the uselessness of her proceeding, and told her that she might as well pat the dome of St. Paul's, for the purpose of pleasing the Dean and Chapter. To make a practical application of this incident, it would be equally useless and absurd to attempt to cure blepharitis by applying remedies to the outside of the crusts.

Simple water will not readily remove these crusts, on account of their greasy character; neither should they be roughly pulled off before being thoroughly softened, as thus the parts beneath are often excoriated and made to bleed. The most satisfactory way of removing these crusts is by the use of a warm alkaline lotion. I usually employ a weak solution of either bicarbonate of sodium or of borax, which I direct to be applied by means of a small sponge or soft rag. The edges of the lids should be thoroughly soaked with this solution until the crusts are softened sufficiently to permit of easy removal. When this has been accomplished, it is well to pass the lashes gently through the fingers, so as to remove all that are loose, instead of allowing them to remain as irritating foreign bodies.

We are now in a position to apply the remedy, and this is perhaps best applied in the form of an ointment. The favorite ointment used in these cases is known to ophthalmic surgeons as Pagenstecher's, its active ingredient being the precipitated yellow oxide of mercury, and the formula would be something like this:—

℞.	Hydrargyri oxidi flav.,	gr. x–xx
	Balsam Peruv.,	ʒss–ʒj
	Vaseline,	ʒj.
M. Bene.		

It is sometimes difficult to get druggists to rub this up as thoroughly as it should be done, and physicians should be explicit in their directions on this point.

Another favorite prescription of mine, and one which patients like very much, because it is not irritating, as the yellow oxide is, if it gets into the conjunctival sac, as it is almost sure to do, is:—

℞.	Acidi boracic,	gr. xl–ʒj
	Vaseline,	ʒss.
M. Bene.		

Either of these ointments may be applied to the edges of the lids by means of the tip of the finger or by the use of a camel's hair pencil. If applied at night, it is allowed to remain until the next morning, when it is washed off with the alkaline lotion mentioned above. If this line of treatment is faithfully carried out, improvement is usually manifest in the course of a few days.

It is surprising to one who has never had his attention called to the subject, how many cases of blepharitis are caused and kept up by refrac-

tion errors. It is almost invariably the rule for me to examine the state of the refraction when a case presents itself of this kind, and I generally find some hypermetropia or astigmatism. I have cured many cases of blepharitis with no other treatment than the necessary correcting glasses, after they had been treated elsewhere by lotions, collyria, and ointments, without number. A very interesting and instructive paper might be written on this subject of the relation of refraction errors to inflammations of the lids. It would, therefore, be advisable in all cases where the above indicated line of treatment fails, for the physician to send his patient to the specialist to have the state of refraction examined.

Strumous Ophthalmia.

The physician is often called upon to treat cases of strumous ophthalmia, children of a strumous habit, who suffer with sore eyes, and perhaps other evidences of scrofula, but in which the unpleasant condition of the eyes is the most prominent symptom. The lids are red and swollen, with numerous and frequently recurring minute pustular collections about the lashes, with some conjunctivitis and photophobia, etc., not only giving the eyes a very unpleasant appearance, but also preventing the patient from using them with any degree of comfort.

In these cases, in addition to the local treatment as sketched above, the internal use of sulphide of calcium is almost a specific. The good effects resulting from the use of sulphide of calcium in scrofulous sores, suppurating glands in the neck, and similar affections occurring in connection with this strumous diathesis, have been known for some time, this use of the remedy having probably been brought to the attention of the profession by Dr. Sydney Ringer; but it is of more recent date that it has been recommended in cases of blepharitis and strumous ophthalmia.

I have employed it in a number of cases and with very satisfactory results; and, although my experience with it has not been sufficiently extended to be able to express a decided opinion, yet I feel that this remedy is destined to be a valuable one in the treatment of this class of cases. The testimony of others as to its efficacy is being gradually collected, and sulphide of calcium is assuming a high place in the therapeutics of strumous ophthalmia, blepharitis, phlyctenular keratitis, etc.

Of course, there are some cases it will fail to cure, but it often happens that the exception proves the rule. There are some cases of ague that quinine fails to cure, and yet no one doubts the value of quinine in the treatment of ague. But even though there are some cases of strumous ophthalmia that sulphide of calcium will not cure, yet I think it cannot fail to be at least of partial benefit in every case, so that it should always be given a fair trial.

The consequences of blepharitis are many and interesting: Trichiasis and distichiasis (in which the lashes turn in and rub over the eyeball); entropium and ectropium (in which the free edge of the lid is respectively inverted and everted). These diseases all call for surgical interference, and need not be considered here. I desire here to place on record the history of a case of one of the more unusual sequences of blepharitis, viz., madarosis, in which the edge of a considerable portion of the lid is completely deprived of lashes, a condition which is usually considered incurable.

A Case of Complete Madarosis of the Upper Lids.

E. S. J., a student, aged 18 years, gives the following history: In the spring of 1878 his eyes were very sore. No physician was called, but the inflammation was treated with domestic remedies. He remembers that his eyes were tied up, that he was kept in a dark room for some days, and that the eyelashes came out very freely. In a short time, however, his eyes recovered from this inflammation, the only sequel being the entire absence of lashes from both upper lids—a condition of complete madarosis.

In the following year he suffered somewhat from symptoms of asthenopia, and applied for treatment at the Eye Dispensary of the University Hospital in Philadelphia. No notice was taken by the physicians there of this condition of baldness of the upper lids, nor did the patient himself call attention to it. A convex glass for R. E., and a convex-cylindrical glass for L. E. were prescribed for him, which he was instructed to wear constantly, and which he did, to the relief of his asthenopic symptoms.

During the summer of 1881 he again commenced to suffer with the same symptoms of asthenopia, and soon after he came under my care, complaining that his glasses did not suit him any more, neither for distance nor for reading. Complains of burning pain, double vision, etc., after reading a short time. He comes to me desiring to know whether I cannot give him a better pair of glasses; and it was while examining the state of refraction of his eyes (under atropine) that I discovered this condition of the upper lids.

On questioning him he said that he felt the need of the lashes very much; he felt that his eyes were not adequately protected. He experi-

enced the most inconvenience in windy weather, when, on account of the loss of the lashes, particles of dust and dirt would get into his eyes, in spite of his best efforts to keep the lids closed. He also felt that his eyes were not sufficiently protected against a very bright light. Also complains of a constant burning pain along margins of upper lid. On inspection, I could see several black points, showing the situation of the hair follicles, and on passing the point of my finger along the edges of the lid, I could just detect the faintest trace of roughness. There was no other abnormal manifestation, no thickening of lids, no blepharitis, no trichiasis or distichiasis, no entropium or ectropium.

Inasmuch as this condition had now existed for more than three years, I did not have much hope of bettering it. In fact, the patient did not apply for treatment for that condition, but only to have his glasses changed and made more comfortable. However I gave him the following prescription, and asked him to apply it freely to the margins of the lids every night:—

℞. Hydrarg. oxid. flav., gr. iij
Balsam Peruv., ♏xij
Vaseline, ʒij.
M. Bene.

In less than two weeks' time I was gratified to find that the lashes had commenced to grow; and five weeks after the commencement of the treatment, which was the last time I saw the patient, the lids were provided with lashes of normal length, except for about a space of two lines just in the middle of each lid. He said that his eyes felt much more comfortable since the lashes had grown out, and that he could now protect his eyes from dust and light, but still had the burning pain just at the spot where the lashes failed to grow.

I might say that the glasses I prescribed for him were—

O. D. + 1.75
O. S. + 1.75 s ⌔ —.50 cyl. axis 180°

which proved entirely comfortable, relieving his asthenopic symptoms, and sending him back to his studies again.

Pulvis Kino Compositus in Influenza.

Dr. G. A. Hawkins Ambler says, in the *Lancet*, that he has derived much benefit from the use of the pulvis kino comp. in catarrh. He used it as a snuff. The discharge was stopped in a few minutes, and though it recurred later on, a repetition of the snuffing process was again most effectual, and the following morning all symptoms had disappeared.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF D. HAYES AGNEW, M.D.,

Professor of Surgery and of Clinical Surgery in the University of Pennsylvania.

Reported by Wm. Morrison, M.D.

NECROSIS OF THE TIBIA—ABSCESS OF THE PHARYNX—UNUNITED FRACTURE OF THE NECK OF THE FEMUR—NECROSIS OF THE FEMUR—DOUBLE HYDROCELE—GONORRHŒA—SUPPOSED FOREIGN BODY IN THE TRACHEA.

Gentlemen:—The first case which I have to show you is one of necrosis of the tibia. The tibia is very frequently attacked by necrosis, as is also the femur. The tibia is more exposed than the femur, in consequence of a large portion of it being subcutaneous, so that contusions or blows received upon this part of the bone are liable to set up a slight periostitis, which may involve the bone. The femur, as I have said, is also frequently the subject of necrosis. There the bone is not so much exposed to injury, and I think the disease in many cases, especially those in which there is no constitutional explanation, is due to the fact that the bone is surrounded by muscles of great power, which strip the periosteum from the bone.

(The patient, a young man of about 25 years of age, then stated that the trouble came on suddenly, when he was seven years old. The limb had never been injured. He awoke one morning with a pain in his leg. He was operated on three years ago, but with no benefit. The wound made by the operation did not heal.)

I shall now introduce a probe through this sinus. It has now passed through the external shell of bone and is now on the denuded surface. I am trying to determine whether or not the bone is loose, for until the sequestrum is loose the operation should not be performed. If you operate before it is loosened, you are unable to tell where the dead tissue ends, and the very damage that you do in separating the diseased part is apt to cause a renewal of the inflammation in the sound portion, and another installment of bone goes down. It is better to leave the work, as far as possible, to nature. You have then only to cut through the new bone and remove the sequestrum.

I cannot impart any motion to this bone. I could, of course, cut down and remove all that appeared to be diseased, but I should probably have to repeat the operation. I think it wiser, therefore, to wait. If this man will wait for three months, or perhaps longer, he will lose no time. A man with a limb of this kind can go about and follow his occupation with comparative comfort. One trouble of which he complains is nocturnal pains coming on when he is warm in bed. These are perhaps due to accumulation of blood in the bones during those quiet moments when the blood leaves the surface of the body and goes to the internal organs. During the daytime the capillary circulation is active, there is a large amount of blood forced to

the surface, but at night this peripheral circulation diminishes, the vessels collapse, the blood accumulates in the internal organs and the bones, and the pressure on the nerves causes pain.

Abscess of the Pharynx.

Here is an interesting case. This colored man was attacked four weeks ago with a swelling inside of his throat, accompanied with difficult deglutition—a desire to swallow, but an inability to do so; when he made the attempt to swallow fluid it would be returned, showing that there was some obstruction, some swelling encroaching upon the pharynx, causing a certain amount of reflex irritation, so that when an attempt was made to swallow, this disposition to reject the fluid was noticed.

Looking in his mouth you will see a soft swelling, occupying the lateral wall of the pharynx, just posterior to the last molar tooth. In addition, you will find on the outside of the neck a swelling corresponding to the group of glands occupying the sterno-cleido mastoid region. You also notice that there is a marked pushing out of the carotid artery, the pulsations of which I can easily feel. There is also marked distention of the temporal and external jugular veins, indicating that there is some pressure upon the venous trunks. Again, looking in his mouth, you see two teeth, the posterior one diseased and broken down, and the anterior one in a similar condition.

Frequently you will have trouble in this region following the eruption of a wisdom tooth; coming out late, the dental arch being filled, there is no room for it, and, in consequence of the difficulty in making its escape from the alveolus and the gum, there is produced an inflammation extending forward and backward. This frequently leads to abscess. There is no history, in this case, of difficulty with the teeth, but these decayed teeth may have something to do with the swelling. All growths commencing in this region, and soon implicating the glands on the outside, are suspicious. They are apt to be malignant in their character, and looking at this swelling, the first impression would probably be that it was an affection of this character; but when we consider the history, that it dates back only four or five weeks, and has been accompanied by conflicting phenomena, its benign character is rendered probable. When I press upon the swelling I find that it is not firm, that it is elastic, an elasticity that is always deceptive. It may be elastic from purulent matter, from serum, or from granulation tissue underneath. This elasticity is common in malignant disease. When I press on the inside and make counter pressure on the outside, I find that there is certainly a communication between the two swellings. When there is a question as to the character of a swelling, and when there is reason to believe that it is not malignant, it is always wise to make an exploratory puncture. Just before the lecture I introduced a grooved needle into this swelling, and I found, not blood, as we should have expected if it were a malignant affection, but pus, showing that it is an abscess in the lateral wall of the pharynx.

The proper treatment is to lay this abscess open, but whether or not there is anything behind this can only be determined from future observation. (The abscess was then laid open with a bistoury, and a large amount of pus escaped.)

It would have been impossible to decide with absolute certainty as to the nature of this affection without the exploring needle.

This man should have his decayed teeth removed as soon as possible, as they have been the cause of this condition of affairs.

Ununited Fracture of the Neck of the Femur.

This man says that three years ago he received an injury on the hip, and has not been able to do any work since. He says that his right leg was broken. Looking at his legs, we see that the right is not as large as the left, but this may be from want of use. Placing the limbs together, we see that the right leg is shorter than the left. Measuring from the anterior superior spinous process to the lower extremity of the malleolus, on each side, I find that there is an inch and a half of shortening.

When I attempt to turn the sound limb out, there is a good deal of resistance, but there is scarcely any when I attempt to turn the affected limb. The trochanter major, on the affected side, is one inch nearer the superior spinous process than on the sound side. There are only two ways in which this can occur, one by fracture through the neck of the bone, the other, by absorption of the neck of the bone. There is a crepitus here which is, I think, the crepitus of an ununited fracture, although at this distance of time we must be very cautious in saying to what the crepitus is really due. Now, when he walks the trochanter slips up as soon as he puts his weight on that leg. An ununited fracture of the neck of the femur necessarily interferes with walking, unless supported by a cane or a crutch; but with the assistance of a cane, he ought to be able to walk with comfort. The trouble with this man is that he has not tried enough. This man can, I have no doubt, walk a great deal better than he has done to-day.

This occurred three years ago. He was then only 47, and had not reached that period at which we usually have fractures within the capsule, although I have seen them at the age of 45 years and at 50. If this were a case of intra-capsular fracture we should not expect union, but if it were extra-capsular there ought to have been consolidation.

Necrosis of the Femur.

This lad is a German; age, 9 years. His disease is of one year's standing. We have no history of the case, but, as we see, he has disease of the right thigh bone. The thigh is very much enlarged, and there is a sinus which, I doubt not, leads down to diseased bone. There is also distortion of the limb and considerable shortening.

The first thing we want to ascertain is, whether this is a case of hip-joint disease and the present trouble is secondary to it, or whether it is primary disease of the femur. Without any examination I am of the opinion that it is simply disease of the bone; but in order to satisfy myself I flex the thigh and move it in various directions, and I find that there is no movement communi-

cated to the pelvis. There is no doubt, then, as to its being disease of the femur. The probe reveals dead bone. From this scar on the front of the femur I presume he has been treated with the actual cautery, a practice of little use in this disease.

In a lad of this age separation of the sequestrum takes place more quickly than in the adult. It has very likely reached a stage when it would be proper to remove it. We shall take him into the house and operate at some subsequent period.

Double Hydrocele, Gonorrhœa.

This young man has had these swellings in the scrotum for two years; that on the left side being the larger. They have been examined by transmitted light and found to be translucent. We have, therefore, a case of double hydrocele. He also has a clap; has had it for about a week. He does not want the liquid removed, and you will find, as a rule, when the accumulation is not more than this, and when the tumor is not of sufficient magnitude to cause inconvenience, that the man may go for five or six months longer without the operation becoming necessary.

The operation is simply puncturing the sac and allowing the fluid to escape, or, if the radical operation is desired, injecting into the sac, after the removal of the liquid, a little stimulating fluid, as the tincture of iodine.

What is of more importance to him is, I think, the cure of this urethritis. It is a specific urethritis, and balanitis, for it extends not only over the head of the penis, but also over the prepuce. The discharge began only three days ago. It is therefore young. The best treatment would be an injection of sulphate of zinc gr.j. to water f ℥ j. thrown into the urethra three times a day, holding the orifice of the urethra around the nozzle of the syringe, retaining the injection inside of the canal for five minutes, at the same time rubbing the under surface of the penis with the hand, so as to distribute the injection over every inequality of the membrane. This is strong enough for the first two or three days. After four or five days the strength may be increased to three grains to the f ℥, and if necessary you can go up to five grains, but it is usually not necessary to go beyond three grains. This will cause the discharge to disappear in the course of ten days. There are certain drugs, as copaiba and cubebs, which may be given internally and will facilitate the cure. Ten minims of the balsam of cubebs or copaiba, in capsules, may be given four or five times a day. I am in the habit of making the injections of the maximum strength at once, and then let the patient reduce the strength by water, as required. This makes the expense to the patient much less.

Supposed Foreign Body in the Trachea.

A mother has brought her daughter here under the impression that there is a breastpin in her throat. An attempt, it is said, was made to extract it, and there is a cicatrix in front of the trachea where the incision was made. Mistakes are very easily made in regard to foreign bodies in the air passages, and you should be certain of their presence before resorting to so serious an operation.

She gives the following history: "She is 15 years old; three years ago she swallowed an old fashioned cuff button with a pin about an inch and a half long attached; she had it in her mouth when she threw her head back and laughed and the pin slipped down. The operation was performed six weeks later. Since she swallowed the pin she has had a little cough.

On ausculting her chest I find some moist râles, but not such as you would expect, if there were a body of this size in the trachea. She has never had any violent spasms threatening suffocation. Of course, it is difficult, to say with absolute certainty that there is not a foreign body in the air passage, but I am of the opinion that there is not, because when a body is so situated there is generally, after a time, a profuse discharge and accumulation of mucus in the bronchial tubes, and the whole lung is filled with moist râles. to which signs may be added violent paroxysms of cough and impending suffocation.

Medical Societies.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

A Case of Typhoid Fever, in which Three Relapses Occurred, with Recovery.

BY J. M. ANDERS, M.D.

The patient, Sallie L., aged fourteen years. Her illness began April 10th, 1881. My first visit was made on the morning of July 12th. The history of the case, in the meantime, a period of about three months, was obtained chiefly from the mother, who is quite an intelligent lady. She stated that her child had passed through a grave form of typhoid fever; that for the first three weeks the fever ran very high. There was, during the same period, constantly marked delirium, with diarrhœa, the stools being described as of clay color. April 16th, six days after the onset, a hemorrhage from the bowels occurred, and on April 23d another, both of an alarming character. There was also present a dry cough, and occasional epistaxis. The mother states that the physician then in attendance had given up all hope of recovery. But, notwithstanding this unfavorable outlook, the patient finally rallied, and began to slowly improve, until she had reached the threshold of convalescence.

About the 15th of May she grew suddenly worse, the fever increasing, and the cough becoming more marked.

May 17th Dr. William Pepper was called in for consultation, and a relapse was diagnosed. The symptoms during this relapse were slightly less grave, excepting intense bronchial catarrh, than during the primary attack, and its duration about four weeks. She was left excessively weak, and markedly emaciated.

A very gradual convalescence now set in; indeed, she had made so little progress during the remainder of the month of June, and up to July 6th, that at the latter date she was scarcely able to sit up in bed, and was still very much emaciated. She had returned to solid food two

weeks previously, and her appetite during this time had been very good. On July 9th, the father very imprudently carried her down stairs, and set her on the front doorstep. On the evening of the same day she again became very ill, the symptoms being similar to those attending the first relapse. The visits of her physician had been discontinued, and for two weeks she had no medical attendant.

On July 12th, at 10 A.M., I was called. The first symptom to attract attention was the marked emaciation of the patient. The temperature was 103°, pulse 130°, and weak. There was occasional cough and a slight mucous expectoration. On auscultation, numerous râles were heard over the whole extent of the bronchi of both lungs, showing decided bronchial catarrh. There was considerable tympany and gurgling upon pressure over the right iliac fossa. There was hebetude and slight delirium.

On the evening of the same day, Prof. Wm. Pepper was again called, and, after making an examination of the patient, expressed the opinion that, undoubtedly, a second relapse had set in. Having seen the patient on two different occasions in consultation, the Professor kindly gave me some of the most important and interesting points in the previous history of the case, according with those above given. The subsequent course of the affection left no doubt as to the correctness of Dr. Pepper's opinion. The temperature now, at 6.30 P.M., was 104, pulse 132. Bowels had moved three times the previous day. There was nothing in the treatment but what is well known, and therefore it need not be stated. The eruption was observable on the following day, which was the fourth day of the fever. The temperature up to the tenth day was maintained at from 103° to 103.5° Fahr. in the evening, and 101.5° to 102° in the morning. On the tenth day it was again higher, being 104° at 7 P. M. It then began to decrease steadily, and by the end of the third week the temperature was normal. Simultaneously with the fall of the heat, the bronchial congestion began to improve, and when the temperature had returned to the normal, the râles in the chest had all disappeared. The eruption had likewise vanished. There was no hemorrhage from the bowels during this attack, but moderate diarrhœa. During the fourth week the temperature was subnormal, and at the end of the fourth week, August 8th, there was a return of the appetite, and, though there was extreme emaciation and great weakness, she had fairly entered upon a very slow and gradual convalescence. It should be stated that she was, about this time, put on tonic remedies, and the diet was gradually changed from liquid to the solid forms. There was now extremely slow recovery up to September 8th, and she had been sitting up in bed for a week prior to that date. On that day the weather was exceedingly warm, the thermometer standing at 99° Fah. in the shade; in fact, it proved to be the hottest day of the season. Whether on account of the extreme heat or a fresh infection by the fever poison, I will not now stop to consider; but, at any rate, between the hours of 11 A.M., when I made my morning visit, and 9 P.M., the temperature of the patient rose from the normal to 103⅗°. There was a return of cough, and bronchial râles again filled the chest. The bowels were loose, the patient having passed three typhoid stools during the day. The following morning the temperature was 102 5°. At 8 P.M. 103°. On the morning of the third day a typhoid eruption appeared over the epigastrium and lower part of the thorax, there being only about half a dozen spots. During the subsequent course of the attack no untoward symptoms arose. The temperature chart shows that from the second to the eighth day the evening temperature ranged from 102⅘° to 102° Fah., and the morning was usually 101.5°. Defervescence began on the ninth day, and on the twelfth day of the attack the temperature was normal. Following this, for several days, the morning temperature was subnormal (97.5°). At the expiration of two weeks all the other symptoms had also disappeared. There were no râles in the chest, no diarrhœa or eruption, and the mind was clear. Oct. 1st, convalescence was again fairly established, for the fourth time, and recovery was retarded by certain complications as will be seen hereafter. Already, during her convalescence from the second relapse, I observed that her lower limbs were partially flexed, and on attempting to straighten them, found I was unable to do so. The right could be almost made straight, but the left knee could not be brought within about four inches of the bed. There was no difficulty in making flexion, and the chief trouble appeared to be a contracture of flexor tendons situated at the back of the knee. Passive motion was practiced three times daily, with the use of stimulating embrocations. This treatment soon gave her the use of the right limb, enabling it to be extended perfectly. Though the left was greatly improved she was not able to fully extend it until after she had gained sufficient strength to walk, and had so used it for a week or more.

October 8th. The patient was placed in a reclining chair, being unable to walk or even stand on her feet. The pulse was observed to run up immediately, from 100 to 130 beats per minute. My notes of this date show that there was a want of power of the heart. The first sound being weak and slapping in character, as if the walls were thin and dilated.

October 18th. General condition improving; the patient has gained considerably in flesh and strength. Heart weak, and after sitting up for a couple of hours, or, after walking a short distance, which she was now able to do, with her mother's assistance, the heart's action would be much increased in frequency, the pulse reaching 144 per minute. The rhythm was slightly irregular, but there was no audible murmur.

November 1st. Pulse rate, when sitting, 120 per minute, and the irregularity of the heart has become quite marked since last note. Since October 25th, or one week after, the heart had become irregular, choreic movements of the limbs and muscles of the face were observable. By the middle of November all the choreic movements had disappeared, and almost simultaneously the heart's action became regular and less frequent. As a result of her voracious appetite

and moderate exercise in walking about the house, she now rapidly increased in weight and strength, and by December 1st was practically cured. No doubt the age and lean condition of the patient were conditions favorable to recovery.

Remarks.—Relapses after typhoid fever are not of rare occurrence. Liebermeister observed them in 8.6 per cent. of 1743 cases at Basle; Gerhard, from reports on typhoid fever, in 6.3 per cent. of 4434 cases, and Baümer had relapses in 11 per cent. of 73 cases of the fever.* Double typhoid relapses are much less frequent than single. Thus, *e.g.*, of Liebermeister's 1743 cases, of which 8.6 per cent., or 111, had a single relapse, only four were instances of double relapse. And in only a few instances has a third relapse been reported. Irvine has had an opportunity of studying five of these latter cases,† and in the limited time at my command to prepare this paper, I have not been able to find the records of any other cases, though most probably others have been reported.

Was my case one of veritable triple relapse? Murchison defines a relapse after typhoid fever as a second evolution of the specific febrile process, after convalescence has been fully established. In his article on typhoid fever, Liebermeister says, "It is often difficult to determine, especially at first, whether a new onset of fever is due to relapse or to some local affection. The characteristic manifestations of typhoid fever often reappear later, more or less decidedly, and then a positive diagnosis is easily made."‡

That the patient whose case we are considering had two relapses, no one will question. Let us, then, compare the notes of the case during the last febrile attack with the requirements of this standard. It cannot be doubted that our patient was free from fever at the time of the last seizure, as the temperature had been normal for a period of at least five weeks, and convalescence, though exceedingly slow, in consequence of the greatly reduced condition, was certainly fairly established. It has been stated in the notes that she had been sitting up in bed for a week previous to the last attack.

On the 8th day of September the temperature suddenly rose from the normal to 103° Fahr. This was attended with dry cough, general bronchial catarrh, as evidenced by râles heard on auscultation, and by typhoid diarrhœa. The bowels had previously been moved only once daily. The course of the temperature was typical of mild typhoid fever or a mild relapse, for the two are very similar, except that there was no secondary rise, as is usually the case, and which was present to a slight degree in the previous relapse. The febrile attack was also very short, the temperature having returned to the normal on the twelfth day. But, according to Liebermeister, there are mild cases of typhoid fever in which the fever lasts only sixteen days, and the same author states that the duration of a relapse is usually much shorter than the primary attack. Hence, as regards duration, the fever was quite compatible with a relapse. As was to be expected in the case of a relapse, with the defervescence of the temperature all the other prominent symptoms alluded to subsided. The fact that there was present a typhoid eruption would seem to fully establish the character of the attack. This eruption, which appeared on the third day, consisted of about half a dozen spots, three of which were of good size. These spots corresponded with the observations of Dr. J. M. DaCosta, being coarser and redder. They were also more elevated. Such an eruption can hardly be termed roseola, the color being very like that of our raspberry. The eruption present during the second relapse was of the same description. In a paper * on relapses in typhoid fever, our illustrious DaCosta has also called attention to the transverse markings upon the nails as an aid in the diagnosis of doubtful relapses, in cases that have not come under observation until after the close of the primary attack (Wilson). In the present case, after the last convalescence had nearly terminated, I observed these white markings on the patient's nails, and upon close examination, found there were three distinct transversal white lines, while the fourth was forming at the root. They were not plainly visible on all the fingers, but particularly so on one of the little fingers.

It would appear reasonable to suppose, therefore, that the above facts, in themselves, would place the fact beyond doubt, that the last was a true relapse.

The duration of the entire illness up to the commencement of the last convalescence extended over a period of nearly six months, and including the last convalescence, about two months longer. The total duration of the four attacks of fever is estimated at ninety days. In accordance with the rule, as stated by most writers, the symptoms, during the primary attack, were more severe than during the relapses. After the original, each successive attack, was milder and shorter than the preceding one, thus the duration of the first febrile attack was about thirty-two days, that of the second about twenty-eight days, of the third twenty-one days, and of the fourth only eleven days. On the other hand, the intervals of freedom from fever increased with each successive attack; thus, between the first and second, it was only about three days, between the second and third, upward of three weeks, and between the third and fourth, as much as five weeks. There were no grave complications during the relapses, except, perhaps, the intense bronchitis, and the only sequel was chorea.

Does this case throw any light on the cause of relapses in typhoid fever? There appeared to be an assignable cause for the second relapse, in the fact that the child had been lifted from her bed and carried down stairs and set on the front door step. But Wilson declares that relapse is not to be attributed to error in diet or over-exertion, and that such imprudences are capable of causing recrudescences of fever. The third relapse was, at the time of its occurrence, believed to be due to the extreme heat of the

* Remarks on Relapses in Typhoid Fever. Transactions Phila. Col. of Phys., Vol. 2.

weather, it having been the hottest day of the season. The weather, however, had been almost equally hot a number of days previously, and the patient had not suffered the slightest inconvenience from it, as she repeatedly stated, in reply to my inquiries. There was nothing to account for the first relapse, save specific reinfection. I am of opinion, from the facts adduced, that the cause of the unusual number of relapses in this instance is to be justly ascribed to *fresh infection* by the specific virus or bacillus causing typhoid fever. Typhoid fever is believed, by all the leading authorities, to be contagious through the stools only, and not from fresh stools, but after they have undergone decomposition. Hence, then, secondary infection may be the result of decomposing excrement upon the body of the patient or his linen, or the bedding. Again, it may arise from failure thoroughly to cleanse the bed-pan after usage. It is probable that the most fertile source is the depository for the excrement. There are those who contend that the only way in which the fever can be communicated is from the original source. In the case under consideration, I do not think that subsequent attacks could have resulted from any but the two last named sources, as due attention was paid to cleanliness and changes of clothing.

It will be interesting to note in this connection that on December 11th the patient's older brother was taken ill with the disease, which proved to be a mild attack, and April 7th, or about one year after the girl was first seized, her younger brother, aged 13 years, was likewise taken sick with the same disease. Were the relapses in the case here reported, and the subsequent cases of the patient's brothers, due to infection arising from the original cause, or to specific poison communicated from the decomposed stools of the patients, which, owing to defective drainage, may have remained in the cesspool? A positive answer to this question, if such could be given, would prove a valuable contribution to medical science, but so far as I am able to judge, any theory based upon the data obtained would be merely speculation.

Remarks.—Dr. J. T. Eskridge observes that, as a rule, relapses occurring after mild attacks are severe, and vice versa. Illustrative of this is the case of a young lady who, convalescing from a mild attack, imprudently sat near an open window and became chilled. A relapse occurred and proved unusually severe. Unconsciousness continued seven days, deglutition was impossible, and the patient was necessarily nourished by enemata. In the hospital, when relapses followed severe primary attacks, several terminated in a really much shorter time, and were characterized by the above rule. The phenomena of typhoid fever vary with different epidemics. A point to be especially noticed is that if the ascent and descent of the temperature is regular, the prognosis may be regarded favorably. If temperature is moderately low, yet irregular in its variations, my experience convinces me that an unfavorable prognosis is unavoidable. In one of my cases, lasting six weeks, when the temperature was subnormal on the ninth day, a fatal issue followed. Regarding the pulse, irregular ity of volume is a feature indicative of cardiac weakness, and of evil augury. Irregularity of time is not a condition occasioning undue alarm. This is often due to a condition of dullness, characteristic of the disease, in which the heart itself also participates. Another point regarding temperature, is, that if during convalescence the evening temperature remains subnormal for two or three successive days, relapse may be expected.

Dr. Wittig narrated an instance of a relapse occurring in his practice, complicated by the development of a sternal abscess. This was not evacuated until convalescence was thoroughly reëstablished, when caries sterni was found to exist. In this, as in all diseases, during convalescence, we should especially observe our patients, and endeavor to detect causes of unusual phenomena in the coexistence of complicating affections. Often the systemic resistance to disease is, as it were, balanced, and great care is therefore necessary to guard against disturbance of those functions concerned in the elimination of the materies morbi. Imprudence in diet, exposure, etc., may check a function, result in further enervation, and precipitate a relapse.

Dr. Anders' observations tend to corroborate the experience of Dr. Eskridge, that mild typhoid is apt to have a relapse of a severe type, and the reverse. A mild case followed by a severe relapse and complicated with double pneumonia, and proving fatal, occurred recently. This case was convalescent fourteen days when the untoward symptoms appeared. Regarding the case reported, the temperature preceding the relapse was subnormal in the morning. Evening observations were not made.

Periscope.

Syphilitic Infection from an Oral Chancre.

Dr. J. J. Chisolm reports the following case in the *Maryland Medical Journal*:—

The effects of syphilis are so marked that those familiar with the sequelæ of the initial lesion cannot mistake the appearances, especially when they follow each other in a regular order. An iritis, occurring simultaneously with a widely-spread, copper-colored eruption, indicates too surely a constitutional infection from a well-known cause, with a positive diagnosis of syphilis, regardless of the character of the person who exhibits these symptoms. It may ever remain an unexplained problem how the disease was contracted, but as to the disease itself there can be no doubt. Such facts often come before the physician in large practice. In response to the anxious inquiry of parents as to what this can possibly be, the cautious physician gives it

the name of blood poisoning, keeps his suspicions to himself, administers mercury in some of its many forms, and in the course of time has the satisfaction of removing the conspicuous evidences of this firmly rooted disease.

Such a case is now under my care. At the suggestion of her family physician, a mother brings her daughter, a modest young lady of eighteen years of age, to have an inflammation of the eye treated. For ten days the right eye has been much inflamed, accompanied by severe suffering and serious impairment of sight. She had been told that it was a severe cold in the eye, and that it would soon yield to an eye drop which had been prescribed. No improvement showing itself, and the suffering being unusual for a case of catarrhal ophthalmia, the case was sent to me for treatment. I found a marked case of plastic iritis. A very contracted pupil with much conjunctival congestion. An atropia drop had very little effect in enlarging the pupil, which seemed to be bound in every direction. She had not slept for some nights, on acconnt of the severe suffering. Copper-colored scaly spots were noticed on the forehead and chin. She showed similar spots on the arms, and said that they were on all parts of the body. Two months since she had sore throat, and from that time her hair has fallen out in large quantity. By tapping the anterior chamber and emptying it of its aqueous contents, prompt relief was given to the nocturnal pains; and by leeching, with the administration of salicylate of sodium in twenty-five grain doses every three hours, the acute attack of iritis was promptly relieved. Under the local use of an atropia solution, gr. viij to ℥ j, one adhesion after another was broken up, with finally a perfectly dilated pupil. From having vision excessively blurred she now reads readily *brilliant*, which means that the eye is perfectly restored. She is now taking biniod. hydrarg., in $\frac{1}{16}$ gr. dose, three times a day, and using on the surfaces most spotted a solution of bichloride of mercury in glycerine. The spots from the face have quite disappeared, and those upon the arm are rapidly fading out.

That this is a clear case of constitutional syphilis, there can be no doubt. The chief interest lies in its origin. During the treatment she called my attention to a thickening of the lower lip at and to the right side of the median line. Five months since what seemed to be a fever blister made its appearance on the lower lip. It attained a considerable size, became surrounded by a hard base, and was six weeks in healing. Some of the hardness still remains, five months from the beginning of the lip sore. When the lip became hard the glands under the jaw at chin and at maxillary angles were very much enlarged and so painful as nearly to stop mastication. It was two months from the ulceration that the general symptoms above narrated commenced to show themselves. She does not know why the stubborn fever blister, as she calls it, made its appearance. She does not remember that any one whom she may have kissed had a sore lip, or that any of her friends had any trouble similar to her own. Such accidental transmissions from mucous labial patches are not rare, but in this latitude are very seldom met with.

Brow Ague.

Dr. G. Stanley Murray relates the following case in the *Lancet*:—

J. C., a gardener by occupation, about forty years of age, came to me a short time ago, complaining of intense pain over his right eye. He said the pain seized him regularly every morning, about nine o'clock, and ceased at seven o'clock in the evening, leaving him, during the remaining portion of the twenty four hours, perfectly free from all discomfort. The attack commenced as a slight itching or tingling in the eyebrow, gradually developing into pain, which, as the day advanced, became so intense as frequently to oblige him to give up work and go home.

On examination I found a slight tenderness over the site of the supra-orbital notch (the seat of the pain), but not of any moment. The patient's general health was good, the appetite unaffected, the bowels regular, and the urine normal. In fact, the man complained of nothing but the pain in question. As he informed me that he had been previously treated by large doses of quinine without experiencing any benefit, I put him upon a course of arsenic and iron, in frequent and considerable quantities for several days, with chloroform liniment and belladonna to apply on lint over the tender spot. This having no effect, I then desired him to try tonga. He commenced taking it the following morning, and in the evening came to say that he thought it certainly did him good, as although he experienced the pain as usual during the day, yet it was much diminished in severity. He determined to continue the drug next day, but left word in the evening (on my being from home when he called), to say that during the day he had been as bad as ever. After this I did not see him for a few days, when he came to tell me that the pain had entirely left him. On making inquiries I learned that, finding the pain was as bad as ever during the second day of his taking the tonga, he called at my house in the evening, to say so, but finding I was out, determined to come again the next day. The following morning he was seized, at the usual time, the pain becoming so intense that he was forced to leave off work and go home. On reaching home he became very sick, and vomited violently, bringing up at last what he described as a "vinegar plant," when immediately all pain and sickness ceased. He was, it seems, very desirous of bringing that interesting specimen of the vegetable world to show me, but his wife dissuaded him from "making a fool of himself, bothering the doctor with that disgusting, dirty stuff!" and so, I suppose, the interests of science suffered! He has since been perfectly free from pain, the attacks having left him. He has experienced this trouble regularly for the last twelve years, although it has never passed away in sickness of stomach before, nor has he ever felt any nausea or discomfort during the course of any previous seizures. He said the attack always commenced during the last few days of March or the beginning of April, and lasted invariably nine, nineteen, or twenty-nine days.

I may mention, his right eye is blind, through cataract, with which he believes he was born.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A tract on "Infant Mortality," before us, turns out to be the advertisement of an "Infant Food" vendor. If pretty much all these foods could be dispensed with and infants fed on the food furnished by nature in the breasts of the mother, infant mortality would receive one of the most positive checks discernible.

——"Electricity in Surgery," by Dr. John Butter, is a volume of 109 pp., published by Boericke & Tafel. The author claims that his methods and recommendations are based almost entirely on his own experience. Some of them strike us as suggestive and valuable, but he certainly claims originality in some instances where it does not belong to him, as in the use of the multiple needles for the treatment of nævi, p. 44.

——The compression of the carotids as a remedial measure in epilepsy and maniacal excitement receives a careful discussion by Dr. J. L. Cushing, in a little monograph of 40 pp. He has devised two instruments for effecting the purpose more readily than by the fingers, and narrates several illustrative cases ("Carotid Compression and Brain Rest," published by Randolph & Co., 900 Broadway, N. Y., price 40 cents).

——"Static Electricity as a Therapeutic Agent" is the subject of a paper by Dr. James Knight, of New York City. He emphasizes particularly its value in paralysis, and gives cases which would be clearer were the Doctor's style more intelligible. We are quite at a loss to understand such sentences as the following: "The electric treatment invariably increased the circulation of the blood to a plethoric condition, that in many instances hydragogue cathartics afforded no relief, but required for their relief venesection."

——The subject of "Preventing Disease" is treated by Dr. J. R. Black, of Newark, Ohio, in a lecture recently sent us. He dwells particularly on the importance of hygiene in schools, and the inculcation of temperance principles. The latter, he thinks, can be done effectually by showing young people specimens of "hob-nailed liver," "shriveled blood corpuscles," "bits of the reddened and thickened stomach of the drunkard," etc. Considering that there are quite as many inebriates, in proportion, in the medical profession as in other avocations, we should have but very modest faith in the efficacy of this suggestion.

BOOK NOTICES.

The Psychology of the Salem Witchcraft Excitement of 1692. By George M. Beard, A.M., M.D., etc. New York: G. P. Putnam's Sons. pp. 112.

This book might as well have been entitled, "Myself as Expert in the Whittaker and Guiteau Cases, with Occasional Reference to Salem Witchcraft." We are informed on the first page that it is "the first attempt ever made to lift the subject of witchcraft out of tradition into psychology." Certainly Despine's *Psychologie Naturelle*, and Maury's works on the witchcraft of the modern ages, not to mention the German monographs, deserve more recognition than this. So far as historical research goes, Dr. Beard offers nothing new; and his analysis of the phenomena is full of prejudice and distorted principles. As to what is the main purpose of this book, sensationalism about the Guiteau and Whittaker cases, it is made up of a series of naked assertions like the following: "There is no civilized country, except America, that would have ever tried Guiteau, to say nothing of convicting him," (p. 30). The volume will add nothing to Dr. Beard's reputation as a scientist, and we may add that it will not detract anything from it either.

Brushland. By John Darby. Philadelphia: J. B. Lippincott & Co. pp. 219.

A breezy book, redolent of the soil in newly turned furrows, of the scent of grass and leafy woods, of the strengthening odor of healthy animals. By his fire in his library, on a fashionable street in a great city, a physician sits and calls to memory the incidents of his experience long ago, on a stubby farm; his wrestling with unwilling nature, to subject her to man's wishes, the people and the clouds of those distant scenes. It is not a treatise on medicine, but it contains hints to cure many diseases, some not named in doctors' books; nor is it an agricultural work, but if the farmer reads it he may learn to root out more weeds than grow on his farm. Nowadays everybody wants to be entertained by a story; this is a story that has something in it more interesting than a plot. A few ask for solid thought, something they can carry away with them; if they read this book and do not find it, the miss will be their own. He who buys it and reads it will put it on a shelf in his library which it is handy to reach.

EMIGRANT ABUSES.

It is the duty of physicians to call the attention of the Government to a most crying outrage that is now being perpetrated by certain unscrupulous and conscienceless individuals in England upon emigrants. An outrage, widespread in its injurious results, which are not confined to the poor emigrants alone, but ramify and spread throughout every portion of our land, affecting or liable to affect all the inhabitants thereof. The *Lancet* tells us that there has recently sprung up in England a nefarious traffic with regard to the transportation of emigrants from that country to America, by which the wholesome regulations enforced by the Passengers Act are evaded. The act provides for a systematic sanitary inspection of emigrant quarters on all trans-Atlantic steamers, forbids overcrowding, and ensures that the provisions served out during the voyage are sufficient in quantity and of good quality.

To evade these beneficent regulations, the agents of these unscrupulous companies, when they have secured an adequate cargo, ship the unfortunates across to some Continental port, and embark them in vessels provided by foreign owners. Sometimes they fall into the hands of respectable companies, who, having some reputation to lose, provide reasonably fair accommodations; but more often they are consigned to some company hastily formed to gain some of the overflow traffic from the regular lines during the very busy season, and in such instances the fate of these poor emigrants is truly deplorable. The steerage is filthy, the passengers are packed like sheep, and the food is both scanty and miserable in quality. The inferior officers, who come into contact with the steerage passengers, exercise the greatest tyranny, even going to the outrageous extreme of selling them food and water at the most exorbitant prices.

Recently one of these vessels arrived in New York, when it was discovered that the water given the steerage was brackish, while the children received a rancid mess, composed of condensed milk and salt water. Diarrhœa and dysentery broke out during the voyage, and an epidemic of measles occurred among the children. Eighteen of the passengers died. This condition of affairs not only works individual injury to the emigrants themselves, but is the very state calculated to breed and fasten disease in our own country. We are the ones to suffer, therefore, does it behoove our Government to take energetic measures to correct this evil. We should resent in the most emphatic manner, and in unequivocal terms, this outrage that is being perpetrated upon us.

CARE OF THE TEETH.

How few physicians, to say nothing of the general public, ever give much, or, indeed, any, thought to their teeth. When they are afflicted with a twisting, gnawing, grinding toothache, they will off to the dentist's and have the offending little ivory pulled or plugged; but to the majority of mankind dental hygiene is an unknown art. So long as there is no pain, and we can chew our food, all right, matters are well enough, and we almost forget that we possess such appendages as teeth. The danger of this

apathy in regard to these very important portions of our bodies has been appropriately pointed out by Dr. WILLIAM D. KEMPTON, of Cincinnati, a brief of whose paper on "*Oral* Hygiene," read before the Section on Oral and Dental Surgery," at the late meeting of the American Medical Association, we give elsewhere. According to Dr. KEMPTON, decayed teeth may cause headache, earache, affections of the eye and of the stomach. A case has been reported wherein the diagnosis was made of malignant disease of the inside of the cheek. A small sore, with rough, thickened and hardened edges, persisting for some time, and resisting all treatment, was diagnosed as above stated. An operation was recommended, and the day decided upon.

In the meantime, a surgeon who always made it a cardinal rule to notice *small* things and upon them to build greater, until he reached his conclusions, examined the patient. With his peering eyes, accustomed to discern trifles, he soon saw a small snag, a remnant, almost invisible, of a former molar tooth, directly opposite this ulcer. He recommended extraction of this irritating little mass, and presto! the *malignant* ulcer healed spontaneously. This is only one of many cases that could be cited to prove the great necessity for care of the teeth. Many, in fact, most of the cases of foul breath are due to decomposing food, lodged from a meal, in the inter-dental cracks and in the excavations of decayed teeth. In a word, dental hygiene, as far as we know absolutely at present, consists in the two following conditions:—

1. Absolute cleanliness—never fail to thoroughly brush and rinse the *mouth*, *tongue* and teeth after each meal.

2. The avoidance of very hot food or liquids immediately after having had something cold in the mouth, and vice versa. These sudden changes will tend to crack the enamel, and thus favor dental decay. Again, when brushing the teeth, one should carry the brush well around the roof, sides and base of the mouth, and over the tongue; in fact, as we have previously said, thoroughly brush the whole mouth, so that any dead and decaying epithelium that may be adhering to these parts will be brushed away. Too much stress cannot be laid on this matter of dental hygiene, and it will be well for all physicians to instruct their patients in the rudiments of the science.

NOTES AND COMMENTS.

Diphtheritic Conjunctivitis Treated with Quinine.

In the *Lancet*, Dr. John Tweedy records four cases of pseudo-membranous (diphtheritic) conjunctivitis, in which he derived most satisfactory results from the local use of a solution of quinine. Three of the four cases occurred in men and one in a woman. Two began as purulent conjunctivitis, of gonorrhœal origin, and two were pseudo-membranous from the first. As soon as the nature of the disease was definitely recognized, all other treatment was stopped, and quinine lotion, containing four grains of sulphate of quinine, with a small quantity of dilute sulphuric acid (to effect a solution), to an ounce of water, was alone used. As far as possible the diseased surfaces were kept constantly bathed with the solution, the conjunctival sac being converted, as it were, into a trough, holding the quinine lotion. A bowl of the solution was put within reach of the patient, who was directed to wash the eye frequently, and in the intervals a well soaked compress was kept constantly applied. The house surgeon visited each case three or four times a day, when he would evert the lids and thoroughly cleanse the conjunctival sac with the quinine lotion.

The superficial, disintegrated portions of the exudation were then gently removed with wet lint, care being taken not to aggravate the inflammation by rough handling, or by rude attempts to tear off the false membrane. Usually the quinine lotion was iced. In two cases the local application of powdered sulphate of quinine was tried at first, or sulphate of quinine rubbed up with an equal part of calomel; but in addition to causing great pain, the powder did not seem to be as beneficial as the quinine in solution, and its use was soon abandoned. The virtues of quinine he believes to be specific in the diphtheritic exudation. Three of the cases recorded were at first treated by frequent ablutions, with a five per cent. solution of carbolic acid, and in every instance the pseudo-membranes rapidly spread under these applications, whereas they were immediately controlled by the quinine lotion.

Forced Alimentation in Phthisis.

This question has latterly attracted considerable attention in France, particularly through the clinical experiments of M. Debove, who has been in the habit of giving to such patients milk and eggs exclusively, but in large quantities.

At a recent séance of the Soc. Medicale des Hôpitaux, he informed the Society that he had recently substituted pulverized meat for the former exclusive alimentation by eggs and milk.

He was led to this practice through consideration of the fact that carnivorous animals are less frequently affected with phthisis than herbivora.

M. Debove makes use of powdered meat prepared as follows: The raw meat is placed under a powerful press and all the juice squeezed out, and put one side; the dry meat is then placed in a slow oven and finally reduced to a fine powder, which is carefully sifted. Four pounds of meat give, by this process, somewhat over six ounces of this powder, which may be mixed with or beaten up with eggs, for use in alimentation.

Relatively, considerable proportions of meat thus prepared may be taken on weak stomachs. M. Debove habitually administered, per diem, half a pound of this powder with twelve eggs and a quantity of lentil flour. Phthisical patients thus nourished regain flesh rapidly, and at the autopsy of one of them who died through accident, it was found that there was a commencement of cicatrization in some of the cavities.

M. Dujardin-Beaumetz confirmed the results obtained by M. Debove's method, and stated that he had also found it of inestimable service in two cases of incoercible nervous vomiting.

Oxyuris Vermicularis.

Dr. James P. Kingsley writes about these worms in the St. Louis *Medical and Surgical Journal.* They may exist in considerable numbers, and for a long time, in a child, without attracting notice by any symptoms of importance. The most frequent symptom is scratching of the anus, especially at night, after the child has become warm in bed, an increased amount of mucus at that time favoring the movements of the worms. There are frequent attempts to evacuate the bowel, which, in many cases, results in the discharge of a small quantity of mucus. Often there is such violent straining at stool that the bowel becomes prolapsed. Sometimes the worms migrate into the vagina, and there excite great irritation, inflammation of the vulva and leucorrhœa. In the male they may cause erection and sometimes balanitis, also pain upon micturition and defecation. Since these parasites inhabit the large bowel only, and usually the lower portion of it, they can readily be removed by the use of proper enemata. The best treatment is the daily injection of two or three ounces of lime water into the rectum, together with the occasional administration of a mild purgative, either a teaspoonful of castor oil, or one grain of calomel rubbed up with five grains of sugar, at bedtime. A solution of common table salt injected daily answers an admirable purpose. When there is a relaxed condition of the bowel, evidenced by its protrusion when straining at stool, an astringent injection should be used. In such cases he uses the following:—

℞. Ferri sulphatis, ℥j.
Infus. quassiæ, Oj. M.
Sig.—Inject four ounces every morning.

The mother or nurse must be careful to wash away all the parasites she can find in the folds about the anus. The great itching that comes on after the patient has gone to bed may be effectually relieved by an application, to and within the anus, of the following ointment:—

℞. Iodoform, ℥ss
Ung. zinci. oxid., ℥ss. M.

In addition to local treatment, tonics are usually required, more especially in strumous children. The preparations of iron are decidedly beneficial.

Contagium Vivum Malariæ.

The *Lancet*, in discussing the various causative agents of malaria that have been brought forward by different investigators during the past few years, says that Cuboni and Marchiafava have brought forward some valuable investigations on the blood of patients suffering from the disease. They constantly found spherical, mobile microorganisms, in variable number, and always in the interior of the white corpuscles. At the commencement of a febrile paroxysm small bacilli were seen, bearing a spore at each end. During the progress of the attack these bacilli lessened in numbers, while free spores became more abundant. Richard has found the parasite described some months ago by Laveran to be invariably present in the blood of patients suffering from malaria, and has never seen it in the blood of patients suffering from other diseases. The organism has a special habitat, the red corpuscles of the blood, in which it develops, and which it leaves when it has arrived at a perfect stage of development. In several of his preparations Richard has actually seen the organism

escape from the corpuscle, which remained attached to it on one side, as an extremely delicate circle. In other cases the mobile filaments alone pierced the capsule, within which the body of the organism remained enclosed. Richard suggests that the comatose condition sometimes observed during attacks of endemic fever may be due to the obstruction of cerebral capillaries by masses of these special organisms.

Steatomatous Tumors Obstructing Labor.

In the *Virginia Medical Monthly* Dr. E. N. Chapman relates some instructive cases, in which steatomatous tumors so interfered with the free passage of the child as to constitute serious impediments to natural labor. Examination in these cases revealed a growth springing from the promontory of the sacrum and the adjacent parts, occupying two-thirds of the superior strait, extending into the excavation and terminating in a prominent globular mass the size of a goose's egg. The os uteri was well dilated, and the child's head rested upon the symphisis pubis and against the anterior face of the tumor. A trocar was introduced into the tumor and upon withdrawing it, nothing flowed from the canula, and yet its point moved freely in every direction, showing that a cavity of some sort had been reached. Being laid open by a bistoury, a brain-like substance began to exude. This being turned out by the finger, the tumor collapsed, the child's head dropped into the excavation, and the labor was terminated at once by the forceps. There was no unusual hemorrhage then or afterwards, and the empty walls of the tumor, which had contained a pint, at least, of steatomatous matter, hung loosely from the posterior third of the pelvic brim. Peritonitis subsequently set in and the patient died on the sixth day. The other cases were similar to this one in all essential particulars. In other cases reported the patients made good recoveries.

Inoculation of Leprosy.

The *British Medical Journal* says that a recent number of Virchow's *Archiv* contains an account by Professor Köbner, of Berlin, of attempts to inoculate leprosy on animals. The results were negative, but the experiments possess interest. They confirmed the investigations already made concerning the bacillus of leprosy. He not only found the organism in fresh juice from the tubercles, but found it in preparations that had been many years in alcohol. While these experiments demonstrate nothing positive further than a corroboration of the causative agent of leprosy, yet they constitute one more step toward the elucidation of the nature of this terrible disease.

Correspondence.

Disintegrated Hepatic Calculus.

Ed. Med. and Surg. Reporter:—

Apropos of the above caption, except in the place of hepatic read renal, in June 17th number of this journal, page 659, I am constrained to report the following recent case: J. W., age 48 years; Sunday morning, June 11th, before rising, was taken with sharp, colicky pains in right hypochondriac lower epigastric, extending rather to the front and somewhat to the right side; this was followed by a second and a third paroxysm in the course of an hour. The sufferer, a man of great fortitude and uncomplaining temper (his wife remarking that he never would complain unless something really serious was the matter), kept the bed most of the day, rested well Sunday night, but on Monday morning, on the return of the pain with aggravated symptoms, sent for me. On my arrival, found him calm and free from pain, with some soreness in the region of lower border of liver, tender on palpation, slight bronze shading of the face and conjunctiva; but told me that uniform pressure in an exacerbation relieved the pain; waited some time, but no return of paroxysm. The evil spirit of pain would not rise at my bidding. Gave pills, one-quarter grain sulphate of morphia, to be repeated on the approach of pain; also linimentum chloroformi comp., to be applied to vesication if necessary, and pills cholagogue, in full dose.

Before leaving, however, judging from the severity of the symptoms as described by himself and wife, diagnosis by elimination seemed to me to point unmistakably to biliary calculi, and I so expressed myself.

My patient, a very intelligent man, and fully alive to his condition, perfectly agreed with me (not a very important matter, by the way, but not always attainable). Remained in same condition all day Monday, but I was again summoned at eight o'clock, and found him in great agony. Administered, promptly, mixture of chloroform and ether, 1–2 and grain ½ sulphate of morphia, hypodermically, followed by successive inhalations of the above anæsthetic, and in less than one hour another hypodermic, same quantity; this produced quiet and sleep.

Saw him again at eleven o'clock; restless, vomited, which gave relief; no bile; left morphia pills; refilled four-ounce bottle of anæsthetic; left instruction to *watch* and *wash* stools.

Passed comfortable night; no stools; gave five pills comp cath., U. S. P.; "acted very well;" several evacuations; relieved; called next day to see me; stools washed and found dessert-spoonful of sand, grains size of a pinhead, quite friable. Patient quite well, with the exception of soreness in former seat, which was entirely relieved by hot fomentation; diagnosis confirmed.

Do not see how I could have made a chemical laboratory of my patient's stomach and gall bladder, and made soluble this calculus.

Youngstown, O. J. D. Littlefield, M.D.

Belladonna Poisoning.

ED. MED. AND SURG. REPORTER:—

At about 7½ A.M., June 5th, I was summoned to attend Andrew L., aged thirty-five, who the messenger said was thought to be poisoned. I went immediately, and upon arriving found Dr. Culverson, of this city, already there. Upon inquiring we found that at about 6.30 A.M., Mr. L. had taken a teaspoonful of what he thought to be fluid extract cascara sagrada, but which, from the physiological effects produced, we determined to be belladonna. When first seen by us Mr. L. was in a semi-unconscious condition. Respiration hurried, circulation rapid. Surface of body cool; pupils widely dilated. We immediately gave an emetic dose of ipecac, and repeated every few minutes until we got full, free emesis; also gave stimulants and one-half grain morphia hypodermically. At 7.50, respiration hurried; radial pulse barely perceptible at the wrist; surface of body and extremities cool; pupils still widely dilated. Gave more stimulants. Bathed feet and extremities with mustard water, using friction; also gave one-half grain sulph. morphia subcutaneously. 8.20 A.M. Patient still unconscious. Character of pulse improved, but still feeble. Gave more stimulants. Applied friction to feet and extremities, and applied warm, dry flannels. Administered one-half grain morphia hypodermically. 9 A.M. Patient resting easier, unconscious, warm and perspiring some. Pulse stronger and regular; respiration more natural; pupils somewhat contracted. Gave one-half grain morphia under the skin. 10 A.M. Patient answers questions; called for a drink of water. Pupils still contracting; character of circulation and respiration improved; delirium lessened. Gave one-half grain morphia hypodermically. 12 M. Patient resting easier; all symptoms improved. Complains of dryness and burning sensations in the fauces. 1 P.M. Patient sleeping; circulation and respiration normal. 1.35 P.M. Patient awoke, and, with assistance, walked into another room to attend a call of nature. 3 P.M. Patient was given one-quarter grain of morphia by the mouth. He walked, unassisted, to the privy in the back yard. The case now progressed to complete recovery without an untoward symptom, and on the next day Mr. L. was upon the street attending to his business.

CASE 2.—At same time and place. Carrie L., aged 14, daughter of Mr. L., took three-fourths teaspoonful of the same drug her father had taken. At 7.30 A.M., when first seen by us, Carrie was in a critical condition. The extremities and whole surface of body was cold. Circulation rapid and feeble. Rapid pulse, being imperceptible at the wrist. Respiration shallow and hurrried. Pupils dilated to their fullest extent. We administered an emetic immediately and it acted promptly. Gave stimulants and injected one-third grain sulph. morphia into the arm. Applied mustard to feet and extremities and used friction. Placed heated irons at her feet and around her person. 7.50 A.M. pulsation of radial artery can now be felt at the wrist, but it is very feeble. Pupils still widely dilated. Surface of body still cool. Respiration somewhat improved. Administered stimulants. Applied friction to feet and extremities, and reapplied the heated irons and gave one-half grain sulph. morphia hypodermically. 8.30 A.M. circulation and respiration much improved in character. Whole surface of body and extremities warm. Pupils somewhat contracted. Gave one-third grain morphia under the skin. The case now gradually grew better, but being a child of nervous temperament and delicate constitution, she did not recover as rapidly as her father, but is now all right again and attending to her studies at school. W. C. CARRELL, M.D.

Greenfield, Pa., June 7th, 1882.

NEWS AND MISCELLANY.

AMERICAN MEDICAL ASSOCIATION. MEETINGS OF SECTIONS.

Section on the Practice of Medicine.

TUESDAY, JUNE 6.

The Section on the Practice of Medicine, Materia Medica and Physiology met, according to programme, at the Opera House, at 3 P.M., Tuesday, June 6th, and was called to order by Dr. J. A. Octerlony, of Louisville, Ky.

The first paper read was that of Dr. J. Hilgard Tyndall, of New York City, on "*Home Treatment of Pulmonary Consumption, by General and Local Antisepsis, on the Basis of Strict Individualization.*" Dr. Tyndall being absent this paper was read by the Secretary. Dr. Tyndall's paper started out by saying that pulmonary consumption comprises a number of more or less chronic destructive processes of the lungs, the remote as well as the direct causes of which are as numerous as are the ills that flesh is heir to. Every individual has his own standard of physical well being, his individual physiology. The paper then proceeded at length to give some of the causes which lead to the disease and suggest a method of treatment. The paper is divided into different heads, describing "*Local Antisepsis,*" etc., giving the method of treatment in each case and the result.

At the conclusion of the reading a motion was made to refer the same to the Committee on Publication.

Dr. Davis, of Chicago, desired to know whether the paper was of sufficient importance to entitle it to that reference, and read the law upon the point. He thought no departure had been suggested from the present practice, and no new methods of treatment were mentioned.

The motion to refer was withdrawn, with a motion to refer the paper back to its author, with the request that he publish the same in some medical journal, which motion prevailed.

The next paper read was that of Dr. John V. Shoemaker, of Philadelphia, on "*The Therapeutic Action of Chlorate of Potassium.*"

The Doctor proceeded to say that this powerful, energetic and active drug was discovered about the end of the last century (1786) by Berthollet, and was used for the first time by Fourcroy, in 1796, with the idea that it might transmit some of its oxygen to the body. At its introduction this salt was principally recom-

mended as an antidote to scurvy. Chaussler proposed it as a remedy for croup. It had completely fallen into oblivion, when Dr. Blanche, repeating the experiments made in 1847 by Hunt and West, with this medicine, in the treatment of gangrene of the mouth and pseudo-membranous stomati is, was led to try it in the treatment of pseudo membranous sore throat and croup. He quoted from many foreign authorities, tending to prove the efficacy of the drug in cancroid affections. etc., and said in this country the use of this important remedy had received but little attention, in the way of reported successes from its use, except from a few observers, among whom was Dr. Thomas Drysdale, who, in a paper read before the Philadelphia County Medical Society, in January, 1877, gave a history of some remarkable cures resulting from its use in diphtheria and pseudo-membranous croup. The Doctor then added that he, also, had met with marked and decided success from its internal use in scrofulous skin diseases; likewise, Dr. M. Landesberg, of Philadelphia, had reported very gratifying results from its topical application in epithelioma of the eyelids.

Dr. Shoemaker referred to its internal use, and said that the chlorate of potassium as a remedy in croup and diphtheria has been used with great advantage by many eminent and experienced practitioners, from the time that it was first successfully applied by Chaussier, in 1819, then by Hunt, Blache, Isambert, and Drysdale, and others, up to the present day. It should, in both these maladies, be given in decided doses, in from five to thirty grains, three or four times daily, until the system is thoroughly under the influence of the drug, providing the patient can bear the quantities just named.

He has used the chlorate of potassium with the most marked benefit in phthisis. He does not maintain that it has any curative action upon the disease, but does hold that, in many cases he has seen, it has greatly assisted in prolonging life. It acts in a peculiarly gratifying manner, by soothing the mucous membrane of the throat and gastro-intestinal canal. It increases the appetite, and thus very materially and conspicuously adds to the weight of the body. It changes the impure and unhealthy blood into a purer and better material.

In marasmus, particularly of children, the use of small doses of this salt has a very satisfactory and beneficial influence. He has administered from one to three grains, three or four times daily, to weak and puny infants, who would regain their nutrition, and fatten on its use in conjunction with good food.

This paper gave rise to some discussion, participated in by Dr. Hollister, of Kentucky; Dr. Gann, of New Jersey; Dr. Bennett, of Michigan; Dr. Davis, of Chicago; Dr. Lester, of Missouri; Dr. Boyd, of Indiana, and Dr. Bell, of Kansas.

The discussion was closed by Dr. Shoemaker, in answer to the arguments in opposition to the opinions given in his paper. The discussion was more especially confined to the treatment of cases of diphtheria. Dr. Shoemaker held that chloride of potash was the most effectual remedy, in which he was sustained by several members, while others favored the use of iron and quinine.

Dr. Koffman, of Nebraska, moved that the paper be referred to the Committee on Publication, and made an eloquent plea in favor of his motion, which was adopted by a unanimous vote.

Dr. Campbell, of Georgia, brought up the subject of the deleterious effects of the use of tobacco, and argued at some length to show how its use affected the human system, and suggested its treatment the same as patients are treated who are under the influence of alcohol or opium.

Dr. Cook, of Tennessee, had used tobacco for eighteen years, but gave it up about a year and a half ago, and felt better for it. All desire for it had disappeared.

Dr. J. V. Shoemaker, of Pennsylvania, and Dr. Octerlony also mentioned cases where all appetite for tobacco had disappeared. Without any formal action on the subject the Section adjourned.

WEDNESDAY, JUNE 7.

The first paper was read by Dr. John V. Shoemaker, of Philadelphia, on "*The Treatment of Syphilis by Subcutaneous Sublimate Injections.*"

He spoke at length of the progress in medicine of the hypodermic method of treating diseases, from its first use by Alexander Wood, of Edinburgh, whose experiments date since 1853, up till the present time. The first to use hypodermic injections of mercurial salts was Scarenzio, of Pavia, who was soon after followed by Hebra, Hunter, Lemin, Martineau, etc.

In his practice he said he usually selected for his hypodermic injections a good glass syringe. Experience has proven to him that these were the best, the metal ones being unsatisfactory, owing to the metal becoming corroded in using the sublimate solution; the hard rubber syringes were too fragile to answer the purpose, it needing but slight manipulation to break them. To these syringes he ordered specially long needles, of the length of 1½ inches or so; his reasons for this were, the other needles are so short they do not penetrate deeply enough, and his object was to penetrate deeply into the subcutaneous cellular tissue. He has learned from the experience of others that the abscess following hypodermic injections of corrosive sublimate was due either to the use of a very short needle, that would not penetrate sufficiently, or to the operator, who may have failed to push it far enough into the integument; and should the latter be the case, the fluid will be deposited in the stratum of the cuticle in which the absorbent vessels are wanting, and inflammation will undoubtedly supervene, causing abscesses. If, on the other hand, the operator has a sufficiently long needle, and will take the precaution to drive it down to the cellular tissue, which is abundantly supplied with absorbent vessels, no injurious effect will follow. He always, in addition, had his patients in private practice to own and carry their own needles, to prevent any possible contagion.

These needles were usually made of steel, and sometimes gold and silver plated; but he always observed that they generally rusted, and he therefore endeavored to use another metal for

the needles and found *gold* to answer every purpose, as it was the only one of all the metals not affected by the sublimate solution.

He uses the following formula:—

℞. Corrrosive sublimate, 1 part.
Distilled water, 100 parts.

In using the first solution he usually began on weak patients with one-eighth grain (10 minims) doses, and continued the same every day until the disease showed signs of abating or the patient experiences the constitutional effects of the drug. In stronger subjects he began the dose at the same quantity, and gradually increased it, minim by minim, every second or third day, until the same result had been obtained. After the patient had received a full mercurial impression in the manner above given in case any of the syphiloderm should still be present, the doses were gradually diminished, just giving a sufficient quantity to keep the system under a gentle influence until all traces of the disease had disappeared. In some of the cases, especially those of an obstinate character, he was compelled to push the drug until he obtained the constitutional effects, which were marked by headache, vertigo, hyperæmia of the mouth, gums and cheeks, increased flow of saliva, difficulty of mastication, disturbances of digestion and diarrhœ, before the syphiloderm would disappear. In others—about nine—who were peculiarly susceptible of mercury, all the constitutional effects followed after several injections of one-eighth grain, although he tried the peptones, chloride of ammonia, water and glycerine—together and separate at various times—without avoiding the stomatitis that Dr. Martineau has since reported did not result in his hands with all the above named combinations. He was always compelled in these cases to begin with one or two minims of the solution and gradually increase the dose, minim by minim, until he reached the point where the patient showed slight evidence of intoxication from the drug, and then decrease it. After using all the various combinations upon the cases under his care, he came to the conclusion that plain water and the sublimate gave him the best results.

He believes this method to be the most speedy and certain way to eradicate syphilis, and prevent at the same time a loss of flesh and vigor of the body that unquestionably follows pouring digestive mercury or iodide of potassium into the stomach. The latter organ, together with the intestinal canal, becomes irritable, the secretions become deranged, and the patient is usually debilitated and broken down in all respects after he recovers from a successful course of syphilitic elimination. The after effect being almost as bad as the former disease, or in case any trace of the syphiloderm remains, the system is too weak to pursue further the internal administration of the drug. It is the belief of Dr. Shoemaker, where the hypodermic use of the sublimate has failed, it has been entirely due to the carelessness of the operator. As a rule physicians do not care to go through the procedure he has just described in giving the injection. They do not seem to share in the desire to make the treatment successful, and as an apology, object to the length of time that would be consumed before the result is reached.

He recommends the subcutaneous method of treating syphilis, because his results have been so good, and from the experiments he has made, his conclusions for its use are:—

First: The *accuracy* and *precision* of the dose. By the stomach corrosive sublimate changes into an insoluble albuminous precipitate, and does not remain long enough in the body to become absorbed, and hence much of it is lost; so, no matter how precise you may be in administering the drug by the mouth, it is almost certain that some of it passes away unabsorbed. By the hypodermic method this is entirely done away with, the precise dose is taken up by the absorbents into the system, and after its object h s been attained is eliminated through the proper channels.

Second: By its use we *preserve* the healthful action of the stomach and bowels; the internal action of the drug on these organs he has already mentioned.

Third: Its *use:* That we may use it in most all cases, in fact, in all, without any baleful results, is conclusive to its application.

In conclusion, he related some of the reasons which render the method distasteful to many physicians:—

First: A dirty syringe or a rusty needle produces inflammation, and an abandonment of the method by one. Again: a short needle or a failure to drive it into the cellular tissue has caused an abscess, and non-success to another. The failure to scatter the solution when injected or to force out the air in the needle, gives pain to the patient and discourages a third. The building up the system with tonics and good food, and the use of the sublimate at the same time, has been overlooked by the fourth, and the results drop below his expectation. The peculiar susceptibility of some persons to certain drugs in very small doses, are lost sight of, the mercury suddenly poisoning the patient, and the physician condemns the method, and so on, *ad infinitum.*

Such, in a few terms, are some of the prominent causes why this potent and valuable method has failed in the hands of some of the American practitioners; and if they would only have patience and try, in an *experimental* manner, by beginning with the very smaliest doses, and continue with great care, their results would be more gratifying. It is not with haste that such methods can be tried and rejected, but one must take time and trouble, and study each phase of its peculiarity, and then with certainty adopt his decision.

Discussion of the paper ensued, participated in by Dr. Gallaher, of Pennsylvania, Dr. Bennett, of Michigan, and others.

On motion of Dr. Gallaher. the paper was referred to the Committee on Publication.

Before adjourning Dr. Shoemaker suggested that some steps be taken to infuse a little more interest in the Section relating to the practice of medicine. It is a shame that it has been neglected for some years past. President Hooper might suggest a remedy.

Dr. Hooper did not know as he could suggest any remedy. If the president of the Section did not feel interest enough in the meetings to

be present, it was not strange that others were not in attendance.

Dr. Shoemaker moved that the Secretary, Dr. Reynolds, be instructed to communicate to the Nominating Committee, asking that for the coming year they will elect officers who will pledge themselves to be present and take sufficient interest in the Section to make it successful in its work.

Dr. Bennett doubted the policy of passing such a resolution, as it might seem to imply censure.

Dr. Hooper said the resolution did imply censure, or otherwise there would be no object in offering it, and we might go forward as usual.

Dr. Whitney, of New York, supported the resolution, as something was necessary to be done. It was not pleasant to waste the time of the delegates in this manner.

Dr. Shoemaker had only the good of the Section in view in offering the resolution.

A running debate took place, and the resolution was finally passed, without a dissenting vote.

After some further general remarks the Section adjourned.

THURSDAY, JUNE 8.

Dr. M. Donnelly, of New York, read a paper on "*Salicylate of Potassa and its Use in Acute Rheumatism and Dyspepsia.*" He said that he had been making some experiments, hoping to find some alkali which could be combined with the salicylic acid and make a more thoroughly alkaline salicylate than that given by the combination with soda. Two parts of bicarbonate of potash and one of salicylic acid dissolved in a small quantity of water gave a neutral solution. The potash was then increased in quantity until one part of the acid united with two parts of potash—about ten grains of acid to twenty grains of potash in a drachm of water—formed a clear alkaline solution. This compound he found very beneficial in the treatment of flatulence, pyrosis and acid dyspepsia.

Dr. Hollister, of Chicago, called attention to the liability of the salicylates in large doses to reduce the force of the heart's action.

Dr. Thomas N. Reynolds, of Detroit, had used salicylate of soda frequently in rheumatism, with marked benefit. The cases must be selected. Climatic and miasmatic conditions often influence very profoundly the course of rheumatism, and we must not rely too conclusively on any one plan of treatment.

Dr. Kyle, of Indiana, thought this drug useful, but considered quinine and iron indispensable in malarious districts.

Dr. J. A. Octerlony thought the salicylates of soda and potash were more particularly applicable in recent and very acute cases, with high fever. In the anæmic and weak, he preferred large doses of tinct. chloride of iron. After adopting a resolution extending a vote of thanks to the Chairman and Secretary, the Section adjourned.

Section on Obstetrics and Diseases of Women.

TUESDAY, JUNE 6.

The Section on Obstetrics and Diseases of Women met at Odd Fellows' Hall, and was called to order at 3 o'clock, by the Chairman, Dr. H. O. Marcy, of Massachusetts.

Dr. Granger, of East Boston, Mass., read a paper upon "*The Mechanical Treatment of Delivery from the Superior Strait.*" His address was illustrated by the exhibition of a modified form of forceps, of his own invention, the novelty being in an appliance or attachment to the ordinary forceps, by the aid of which the author claimed that the head of the fœtus could be depressed while making traction.

Dr. Granger was followed by Dr. Beverly Cole, of San Francisco, with a paper on "*The Forceps and Their Application.*" The author exhibited a forceps of his own invention, for which he claimed the following advantages: The fenestrum of each blade is large at the heel, thus allowing plenty of scalp to protrude through, fixing the forceps so that they will not slip. The shank is very much curved, enabling one to apply the forceps at the superior strait without making pressure on the perineum. The instrument is very light, weighing but fourteen ounces. Dr. Cole then went on to point out the defects in all the forceps now in use. In the discussion which followed the reading of this paper, Dr. Battey, of Georgia, and others, fully endorsed the views expressed by Dr. Cole, and praised very highly his forceps.

Although Dr. P. J. Murphy was unavoidably absent, his subject, "*The Condition of the Cervix Uteri after Emmet's Operation, and Especially it Effects upon Subsequent Gestation and Delivery,*" was taken up by the Section and discussed to the hour of adjournment. The general sentiment in regard to Emmet's operation for laceration of the neck of the womb seemed favorable, when performed by a gynecologist.

A resolution was offered and adopted, requiring members of the Section to furnish a brief of remarks made on the day following their delivery.

WEDNESDAY, JUNE 7.

A paper was read by Dr. Nelson, of Chicago, on "*Especial Pathological Conditions of the Cervix Uteri.*"

Dr. Battey, of Rome, Ga., at the request of the chairman, gave an account of the year's progress in ovariotomy. The session was well attended.

THURSDAY, JUNE 8.

Prof. Dunster, of Ann Arbor University, delivered an address on "*Ovariotomy During Peritonitis, is it Justifiable?*"

This was followed by the report of a case of "*Impacted Retroversion of the Uterus,*" by Dr. H. F. Campbell. Dr. Prince, of Illinois, exhibited a number of obstetrical instruments.

In the absence of Drs. Warren, of Boston, and Cutter, of New York, their papers on "*The Elastic Serrated Uterine Scoop and Curette,*" and "*The Treatment of Uterine Fibroids*" were passed.

Dr. H. O. Marcy then read a paper on "*Treatment of Fibroid Tumors of the Uterus.*" Upon the conclusion of this paper the section adjourned.

Section in Surgery.

TUESDAY, JUNE 6.

This Section organized with Dr. William A.

Byrd, of Illinois, as Chairman, and Dr. Hugh McColl, of Michigan, Secretary.

Dr. Carl Seiler, of Philadelphia, opened the session with some remarks on the uses of electricity in surgery. In his experience the platinum knife of the galvano-cautery, in order to be serviceable, must have a fixed temperature, varying according to the end desired. He has devised an instrument, so arranged that the plates are suspended above the liquid, and can be immersed by means of a treadle, worked by the foot of the operator. In order to overcome polarization, and continue the current for any length of time, he has introduced two cells, containing the same number of elements, which can be alternately immersed by the treadle, thus always exposing a fresh surface to the action of the acid. The thermal cautery cannot be used in many cases, for example, in certain conditions in connection with the turbinated bones, whereas the galvano-cautery knives can be made so delicate as to enable the operator to reach any point.

Dr. William Hill, of Bloomington, Ill., read a paper on "*Abdominal Section for the Relief of Intestinal Obstruction, due to Intussusception.*" The author first operated successfully August 23d, 1855. The case was one of ileo cæcal invagination in an adult.

Dr. Peck, of Iowa, reported a recent case, that promised well.

Dr. Halley, of Kansas City, reported two cases, both of whom died, but he, nevertheless, considers it a justifiable operation when per formed early.

Dr. Lee, of Chicago, advocated early operation, and said that in making a diagnosis too much reliance must not be placed on the pulse and temperature, because in some of the gravest cases they are undisturbed.

Dr. Gay, of Buffalo, read a paper on "*Anchylosis of the Hip in the Straight Position.*" He discussed the two surgical measures of treatment, subcutaneous osteotomy and fracture, the latter of which he regards most favorably. This paper elicited much discussion, and the opinion of the Section was about equally divided as to the merits of the two measures mentioned.

Dr. Jos. H Warren, of Boston, read a paper on "*A New Truss to be Applied after the Radical Cure of Hernia.*" The truss consists of a concave wire gauze pad, with more gentle springs than usual. The pad is surrounded with a rim of tubing and a bridge of tubing extended across to strengthen it. It draws the pillars of the hernial rings together.

WEDNESDAY, JUNE 7.

Dr. J. F. Stewart, of Peoria, Ill., presented a *Splint for Fracture of the Elbow.* It was a wooden hinge splint, with steel side rod and adjusting screw, and the author claimed that it is applicable to all forms of fracture of this joint.

Dr. George W. Nesbitt, of Sycamore, Ill., followed with a paper on "*Ununited Fracture of the Femur Treated by Exercise.*" He reported a case in which union failed to take place and was not secured until the limb was put in a plaster-of-paris splint, and the patient compelled to walk without crutches, all other means having proved useless. Several similar cases were reported in the discussion which followed. Dr. L. A. Sayre, of New York, advised that the plaster-of-paris splint be applied at once, for he had never seen a case in which it had done harm when properly applied and carefully watched; if, however, swelling had occurred before he reached the patient he would wait until it had subsided.

Dr. John L. Atlee, of Lancaster, Pa., spoke of the advantage of placing woolen fabrics next the skin before applying the plaster bandages.

THURSDAY, JUNE 8.

Dr. Jos. Ransohoff, of Cincinnati, read a paper entitled "*Contribution to the Surgery of the Liver.*" The paper consisted in the recital of two cases. The first, one of hepatic calculi, where he had opened the abdomen, cut into the gall bladder and removed the calculi. The wall of the gall bladder was stitched to the abdominal wall before the former was opened. The incisions were made with the galvano-cautery, in order to avoid hemorrhage. The second was one of hepatic abscess, in which repeated aspirations did no good. The abdominal cavity was opened, the wall of the abscess stitched to the abdominal parietes, the sac opened, washed out by a constant stream of water and several large sloughs removed. The result was good.

Dr. Edmund Andrews, of Chicago, read a paper on "*The Proper Points for Incision in the Drainage of Suppurating Knee Joints.*" The anatomy of the knee joint was reviewed. Dr. Andrews said there were three cavities: 1, the submuscular bursa; 2, the supra-patellar; and 3, the infra-patellar. Into these an incision was made upon each side, and short drainage-tubes introduced from each direction. There were eight points of incision referred to in order to make the drainage complete; two, one on each side of the bursa; two, one on either side of the supra-patellar expansion; two, one on each side near the posterior part of the joint; and two, one on either side of the ligamentum patella.

Dr. Byrd, the Chairman, read a lengthy paper on "*Excision of the Intestinal Canal when Covered with Peritoneum.*" The author sums up the whole subject as follows:—

First.—Resections of the small intestine may be done to a considerable extent without interfering in any appreciable degree with digestion.

Second.—Practiced under suitable conditions the operation is to be considered perfectly legitimate.

Third.—The resection may be performed by bringing the divided ends directly into apposition and closing the abdominal wound, by forming an artificial anus. The second and third procedure expose to less subsequent danger.

Fourth.—Resections of fibrous and cicatricial structure, which are probably more frequent than is generally supposed, may cause a radical cure, and the same is the case with epithelioma. On the contrary, resection of cancerous obstructions gives only temporary relief, and at a greater risk.

Fifth.—By proper diet after the operation the risk of fecal extravasation may be reduced to a minimum, and the best diet for this purpose is one containing as little fluid as possible.

Sixth.—By introducing liquids per anum, and drink in the same way, water is absorbed as by the mouth, and there is no sense of thirst; the flow of intestinal fluids is less, considerably, and the patient is more comfortable.

This paper gave rise to much discussion, after which the Section adjourned.

Section in State Medicine.

This Section organized with Dr. A. L. Gihon, United States Navy, as Chairman, and Dr. J. H. Sears, of Waco, Texas, Secretary.

A discussion took place upon vaccine virus, without any result.

Dr. John G. Lee, of Philadelphia, then read a paper on "*Suicide in the City and County of Philadelphia during the last Decade.*" From December 31st, 1871, to January 1st, 1881, the proportion of suicides to the total number of Coroner's inquests was 53 to 1000. Suicide occurred most frequently among the married of both sexes. The greatest number were between the ages of thirty and fifty years. The methods of suicide in 636 cases were: hanging, 119 males, 22 females; shooting, 114 males, 8 females; laudanum, 79 males, 17 females: cutting throat, 70 males, 13 females; drowning, 46 males, 11 females; arsenic, 11 males, 8 females; the remainder took their lives in various ways.

Dr. Smith, of the United States Army, followed with a paper on "*Sickness and Mortality in the Army,*" the salient points of which are as follows.

The paper opens with two questions:—

1st. Has State Medicine progressed within the past few years?

2d. Has its progress been marked by a diminution of disease and death?

His answers are made up from an analysis of the Surgeon General's reports of disease and death in the army, from 1871–1881, both inclusive. Every man in the army was sick over one and one half times per year, on an average, since the sick rate per year was 1598 per 1000. The death-rate was 8.71 per 1000 of mean strength per year, while the death rate for the sick was 4.63 per 1000. The sickness among the white and colored troops was as 1551 of the former to 1498 of the latter, while deaths were as 845 white to 1104 colored. These statistics seem to show an advance in army sanitation and therapeutics in the past eleven years. Fewer men, in proportion, are now taken sick; fewer men now die than were taken sick and did die eleven years ago.

"*Expert Medical Testimony*" was then brought before the Section, and was fully discussed.

Dr. Hibbard offered the following resolutions, which were adopted and referred to the Association in general session.

Resolved, That the Section of State Medicine deems it advisable, and more conducive to the ends of justice, that medical men called as expert witnesses should be subpœnaed directly by the court, instead of, as now, by either side.

The temperance resolutions presented to the Association in general session, and referred to the Section on State Medicine, now came up for discussion, and finally the following resolutions were adopted:—

Resolved, That in view of the alarming prevalence and ill effects of intemperance, with which none are so familiar as members of the medical profession, and which have called forth from eminent practitioners the voice of warning to the people of Great Britain concerning the use of alcoholic beverages, we the undersigned members of the medical profession of the United States unite in the declaration that we believe alcohol should be classed with other powerful drugs; that when prescribed, it should be done with conscientious caution and a sense of great responsibility.

Resolved, That we are of the opinion that the use of alcoholic liquors as a beverage is productive of a large amount of physical and mental disease; that it entails diseased appetites and enfeebled constitutions upon offspring, and that it is the cause of a large percentage of the crime and pauperism of our cities and country.

Resolved, That we would welcome any change in public sentiment that would confine the use of intoxicating liquor to the uses of science, art, and medicine.

Dr. C. M. Hughes, of St. Louis, followed with a paper on the "*Rights of the Insane.*" He maintained that the insane are entitled to medical inquiry by medical methods. He believed that the criminal insane should be confined for life, and be prevented from extending their disease to posterity. At the close of this paper the Section adjourned.

Section on Ophthalmology, Otology, and Laryngology.

TUESDAY, JUNE 6.

This Section met at Market Hall.

At the annual meeting of the American Medical Association, held at Chicago, in 1877, Drs. Reynolds, of Louisville, and Scott, of Cleveland, introduced a resolution providing for the organization of a Section on the above-named subjects. The following year the organization was completed by the election of Dr. Herman Knapp, of New York, as Chairman, and Dr. X. C. Scott, of Cleveland, as Secretary. The officers for the present year are Dr. D. B. St. John Roosa, of New York, Chairman, and Dr. S. Cohen, of Philadelphia, Secretary. In the absence of the Chairman, Dr. Cohen called the meeting to order. Prof. S. B. Jones, of the Chicago Medical College, was elected Chairman. At his own request, Dr. Cohen was excused from the duties of Secretary, and Dr. Carl Seiler, of Philadelphia, was chosen to fill the position.

Dr. W. Porter, of St. Louis, then read an interesting paper on "*Recurrent Pharyngeal Hemorrhage.*" He related two cases, in which there were evidences of incipient phthisis. The bleeding was slight, but oft repeated. In both cases the hemorrhage was found to come from the tonsillar arteries, and was readily controlled by styptic applications. These cases teach the lesson that, in all cases of supposed hæmoptysis, the larynx and pharynx should be carefully examined.

Dr. Carl Seiler, of Philadelphia, had seen

three cases in which bleeding from the upper pharynx and naso-pharynx had been mistaken, by the patient himself, and by others, for bleeding from the lungs.

This paper gave rise to some discussion, after which Dr. X. C. Scott, of Cleveland, made some remarks on the "*Use of Powdered Iodoform in the Treatment of Diphtheritic Conjunctivitis.*" He applied the iodoform to the surface in fine powder, once a day, and since commencing this treatment has not lost a case.

Dr. Porter found it very beneficial in syphilitic ulceration of the skin of the nose.

Dr. Seiler thought it a very valuable drug, but had been utterly unable to permanently destroy its odor, and was, therefore, compelled to abandon its use.

WEDNESDAY, JUNE 7.

Dr. Seiler, of Philadelphia, exhibited some galvano cautery instruments for operations in the larynx, pharynx and nasal cavities. He has substituted vulcanized fibre for silk, as an insulator on the conducting wire, because the silk is apt to be burned off by the heat generated in the wires, thus allowing the heated wire to scorch parts that are not intended to be touched.

Dr. Calhoun, of Atlanta, reported a case of "*Accidental Vaccination of the Eye,*" occurring in a little boy, who, having gotten some virus from a vaccine pustule on his fingers, subsequently scratched his eye. The cornea was destroyed.

Dr. Johnson, of Peoria, reported a case of "*Dislocation of the Lens Under the Conjunctiva*" from traumatism.

Dr. Connor, of Detroit, reported a case of "*Tumor on the Base of the Skull.*" The first symptoms noticed were gradual loss of hearing and vision on the affected side. The patient died, and a large tumor was found on the base of the skull, which had caused absorption of the contiguous brain tissue, up to the optic thalamus, which was destroyed. Interesting cases were related by Drs. Agnew, of New York, and Johnson, of Chicago.

THURSDAY, JUNE 8.

Dr. Turnbull presented a paper on "*Hearing in Children,*" which was read by title.

Dr. H. G. Young then opened the discussion on "*Communicable Eye Diseases,*" which was participated in by Drs. Hazen, Smythe, Johnson, Connor, Jones and Dyer. Dr. Dyer offered the following resolution:—

Resolved, That a committee of three be appointed to consult as to the best means of bringing reliable information before the public, with a view of preventing the spread of communicable eye diseases. The chair then appointed Dr. Jones, of Chicago; Dr. Dyer, of Pittsburgh, and Dr. Connor, of Detroit, as the committee to report at the next meeting. The session then adjourned.

Section on Diseases of Children.

This Section organized with Dr. William Lee, of Baltimore, as Chairman, and Dr. E. C. Miller, of Iowa, Secretary. Dr. N. S. Davis, of Chicago, read a paper on "*The Means of Lessening the Mortality of Infants from Bowel Affections.*" This lengthy address was so full of interest that it deserves a somewhat full report. The speaker said that the importance of this subject cannot be over-estimated when we remember that one-third of the human race die under five years of age, and that a large percentage of these deaths are due to bowel complaints. Food, drainage, ventilation, etc., are under our control, but there are certain conditions that are not. Thus meteorological conditions of the atmosphere, whether they refer to impurities, sudden changes, or waves of continuous high or low temperature, are not under our control and yet we can do much to mitigate their evil effects Most recent writers class cases of serous diarrhœa and cholera morbus in children under two years of age, under the name of catarrhal gastro-enteritis, and while they state that these diseases are most common during the warm months, they give as causes, improper feeding, impure and changed milk, impure air, teething and over-worked, badly fed, and unhealthy mothers. Dr. Davis says that bad milk and food are prevalent in all communities during the winter as well as the summer. Children cut their teeth in December as well as in July, and unhealthy mothers exist at all times of the year. If any of these causes produced cholera infantum it would be frequent at all times. Statistics demonstrate that the prevalence of all grades of these two diseases are almost restricted to the period between the last week in June and the last week in September. In Chicago, in 1872, the records show, 8 deaths in April, 6 in May, 23 in June, 246 in July, 163 in August, 69 in September, 13 in October, and 2 during the rest of the year. Other years show the same results. The diseases prevail very little in cities where the change in temperature from the warmest days of summer to the coldest days of winter is very slight, and where sea breezes and other causes make the nights cool. The milk distributed in San Francisco and New Orleans is the same as that in Boston and Chicago, and the nursing mothers are no more free from mental and physical infirmities. Statistics show a ratio of only about five deaths from cholera infantum annually, for every 10,000 inhabitants in San Francisco, seven in New Orleans, twenty-five in Boston, and thirty in Chicago. There must, therefore, be some cause not common in all large cities. A record of the disease and coincident meteorological observations were carried on for three years in Cairo, Davenport, and Omaha. The reports of these observations, published some years ago, showed:—

First.—That the prevalence of the affections under consideration is limited principally to July, August and September, commencing with the first wave of high atmospheric heat that continues days and nights for more than five days, which, in the latitude of Chicago, is sometimes the last week of June, but more frequently the first week in July, and continues more or less during the succeeding ninety days.

Second.—That while the deaths from these affections in any city or given community will be nearly the same in the two first months after they begin in July and August, the date of the initial symptoms or beginning of the disease, in three-fourths of all the cases, will be in July, very few originating after the first of August. Many cases commencing in July continue until the months

of August or September, causing wasting and death.

Third.—That it is not simply high or extreme heat, of temporary duration, such as that of a single day, or any number of days, with cool nights, which favors the development of the disease, but continuous high temperature, day and night, for several days; and if, in addition to the heat, the air be stagnant, from lack of winds or obstructions, as in large cities, or from defective ventilation, the effect is greatly increased. This explains why these affections are more numerous and fatal in cities than in rural districts, and why they prevail so little in even large cities located in warm climates, provided the location be such as to afford cool breezes at night.

Fourth.—That while the great majority of attacks which occur in any given summer are found to have their beginning in July, or during the first thirty or forty days after the first wave of protracted high temperature for the season, they are not equally distributed over the whole of the month.

We have the physical law that the higher the temperature of the air the rarer it becomes and the less oxygen is contained in it, therefore one breathing at a high temperature would receive less oxygen than at a low temperature. Stagnant air becomes more rapidly exhausted than that which is moving, and the physical law of expansion by increase applies to the living as well as to dead matter; consequently high heat tends to increase the distance from each other of the atoms of the human body, thereby lessening the force of vital affinity and increasing the susceptibility to impressions. The capacity of the blood for taking up oxygen depends greatly upon the quantity of saline ingredients it contains, and under a continuous high temperature the cutaneous exhalation is so great that the blood becomes depleted of these ingredients. Colitis and recto-colitis seldom occur until late in the season, when warm days are followed by cool nights. If these premises are correct, it follows that our efforts to lessen mortality from these diseases must be directed toward securing for young children a better supply of fresh, pure air, for increasing the oxygenation and decarbonization of the blood, maintaining the activity of the vaso motor system, and counteracting the effect of high temperature by increasing the general tonicity and lessening the excitability of the tissues. To secure these conditions he recommends better ventilation of dwellings and especially nurseries and sleeping rooms, during the warmest parts of the summer. The sending of young children from densely populated districts to moderately elevated country locations or to floating hospitals, receiving ships or large bodies of water during the period of special high temperature. *The judicious use of the sponge bath.* Whenever the system is relaxed and rendered morbidly sensitive by continuous high temperature, causing the infant to be languid, restless, and sometimes pale, a free sponging of the whole surface with water, as cool as is comfortable, always produces an invigorating influence, which will last from six to twelve hours. It is well known to every careful observer that a large majority of all the attacks of this disease show their first beginning during the last half of the night or early morning, owing to the long continuance of high temperature and the confined air of the night. The increased tone of the whole vascular system produced by a sponge bath at bedtime would enable thousands of these little sufferers to pass the whole night unharmed, when without it the dread weakness would begin.

This interesting and valuable paper was followed by one read by Dr. William Lee, of Baltimore, on "*Observations on Rickets,*" which elicited much discussion, after which the Section adjourned.

Section in Oral and Dental Surgery.

TUESDAY, JUNE 6.

The Section organized with Dr. D. H. Goodwillie, of New York, as Chairman, and Dr. Truman G. Brophy, of Chicago, Secretary.

Dr. William D. Kempton, of Cincinnati, read a paper on "*Oral Hygiene.*" He said that the profession is indebted to specialists for many, if not most of the important discoveries. Oral hygiene was very important, and the results of its neglect manifold. Many of the cases of headache, earache, affections of the eye and stomach, are oftentimes directly traceable to badly decayed teeth. The paper closed with directions for the preservation of teeth, and the speaker strongly urged physicians to impress upon their patients the necessity of care of the teeth.

During the lengthy discussion which this paper elicited, Dr. Allport made the remark that our food should be taken as nearly as possible in the condition in which God has prepared it. He stated that the so-called patent process of making flour eradicated much of the phosphate in the wheat, and remarked that the enamel of the teeth is composed mainly of phosphate of lime. After the discussion terminated the Section adjourned for the day.

WEDNESDAY, JUNE 7.

"*Heredity in Dental Development*" was illustrated by the report of a case by Dr. W. C. Barrett, of New York. After which, Dr. J. S. Marshall, of Syracuse, N. Y., read a paper on "*The Need of Dental and Oral Surgeons in the Army and Navy.*" Attempts have been made at various times, in Congress, to secure legislation toward accomplishing this result, but nothing has yet come of it, save the appointment of a dental surgeon at the Naval Academy, at Annapolis. Soldiers on the frontier, and sailors on a long cruise have no opportunity to have their teeth attended to. The objection always urged to such appointments was the small number of men requiring dental treatment. Statistics were quoted to show the fallacy of this argument. The paper closed with the recommendation that a committee be appointed to arrange a statistical report of all dental and oral diseases, and request the surgeons-general of the Army and Navy to incorporate them in their regular reports. This address elicited much discussion, and finally, the following resolution, offered by Dr. Allport, was adopted: That a committee of three be appointed, who, in connection with Dr. Maynard, of Washington City, and the surgeons-general of the Army and Navy, should make what efforts

they deemed advisable regarding the appointment of dental and oral surgeons in the Army and Navy, and to report to the Association next year." Drs. Allport, Williams and Marshall were appointed the committee. Dr. Lawrence, of New York City, offered a resolution calling for the appointment of a committee to consider the subject of food, including insalivation, mastication, digestion and assimilation, in its relation to the development of the different tissues and organs of the body. Drs. Lawrence, Kempton and Talbot were named the committee. The Section then adjourned for the day.

THURSDAY, JUNE 8.

Dr. Goodwillie presented wax models of three cases of necrosis from arsenic. In one case there were abscesses in the superior maxillary bone at nearly all the teeth, caused by applying arsenic to destroy sensibility of the dentine before plugging the teeth.

Dr. Eugene S. Talbot, of Chicago, followed with a paper on "*The Injurious Effects of Mercury as Used in Dentistry.*" He thought there could be no doubt that amalgam fillings in teeth will sooner or later produce mercurial poisoning, though years may sometimes elapse before the injurious effects are felt. He related two cases in which the symptoms of mercurial poisoning were well marked. The amalgam fillings were removed, gutta percha inserted, and subsequently the teeth were plugged with gold, when all toxic symptoms disappeared. He concludes, from experiments, that mercurial vapors are given off from amalgam fillings at all ages, and from all varieties: even in sixteen year old fillings the vaporization was sufficient to respond to chemical tests; that mercury, when inhaled into the lungs is far more active than when taken into the stomach; and that physicians, when treating dyspeptics, anæmics and persons suffering from nervous debility, would do well to examine the mouths of patients, to see if artificial teeth on red rubber, or pluggings of natural teeth, may not have some compound of mercury in their composition.

Dr. W. W. Allport, of Chicago, followed with a lengthy paper entitled "*How Dentists Should be Educated.*" He claims that the dentist should be educated both in mechanical dentistry and oral surgery. The oral surgeon who desires success, must have a complete medical education, coupled with a special knowledge of dental surgery. He concluded by saying that all dental and oral surgeons should, having primarily received a medical education, become legitimate specialists in its practice, and all medical graduates should be thoroughly instructed concerning diseases of the teeth.

Dr. J. B. Lawrence, of New York, followed with a paper on "*Medico-Dental Science,*" after which the Section finally adjourned.

Can Dreams be Controlled?

The *Lancet* says that a French investigator, M. Delaunay, finds, from experiments upon himself, that the character of his dreaming may be controlled by stimulating various portions of the brain by means of heat. By covering his forehead with a layer of wadding he gets sane, intelligent dreams. He has also experimented on modes of lying, which favor the flow of blood to particular parts, increasing their nutrition and functional activity. He has observed that the dreams he has while lying upon his back are sensorial, variegated, luxurious. Those experienced when on the right side are mobile, full of exaggeration, absurd, and refer to old matters; but those produced when on the left side are intelligent and reasonable, and relate to recent matters; in these dreams one often speaks. These observations may be correct, so far as M. Delaunay is concerned, but most people who venture to lie on their back, especially after eating, are apt to find their dreams anything but luxurious.

Death from Chloroform.

A death recently occurred in Charleston, S. C., under circumstances that plainly demonstrate the danger of administering chloroform unassisted. A woman was to be operated upon, and the surgeon took with him two assistants. She refused to allow them in the room. The operator told them to wait in the parlor until she was chloroformed and he would then admit them. Upon admission one of the physicians was asked to look after the chloroform; he placed his finger on the radial and found the woman pulseless; she was dead. All efforts at resuscitation were unavailing.

Medical Experts.

A medical expert called for the defense in the recent celebrated Malley case, was asked by the prosecuting attorney, "Have you not written plays for the stage?" "Yes sir." The attorney, with a deprecating shrug, looked toward the jury and sneered, as though to say, "You can plainly see how little this man's evidence will be worth, when he has sunk so low." Experts beware; not of the respectable stage or of its literature, but of this cynical New England attorney.

Items.

—Professor Henry J. Bigelow has resigned the Chair of Surgery in Harvard University. He has been connected with the school for thirty-three years.

—Virchow defines *tubercle* as "a neoplasm, which takes its origin from the connective tissue, in the form of nodules, consisting of closely packed cells."

—*Student.*—"How is it, Doctor, that I always take cold in my head!" *Doctor.*—"It is a well-known principle, sir, that a cold is most likely to settle in the weakest part."

—A quack doctor, on his death-bed, willed his property to a lunatic asylum, giving as a reason for so doing that he wished his fortune to go to the liberal class who had patronized him.

—Two physicians applied a galvanic battery to a colored boy in Richmond, Va., who was said to have been struck dumb for lying to his mother, and he quickly began to talk, in the most distinct and emphatic manner.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

TREATMENT OF PLEURAL EFFUSIONS.

BY D. LONGAKER, M.D.,

Of Philadelphia.

The product of inflammation of serous membranes may be said to consist of fluid and cells; the varying relative quantities in which each of these is found constituting, when the pleura is the seat of the disease, respectively, fibrous, serous and purulent pleurisies.

It is not my object to enter into any discussion of the causative and pathological relations of these, b[illegible]e treatment of certain conditions shall claim our attention, and these, the presence of a small, moderate, or large amount of effusion.

Where the effusion is small, or in other words, where it is a dry pleurisy, and on the other hand, where it is extensive, the indications are decided and positive. It is the instance of a moderate effusion which forms the debateable ground.

We often find, in the course of an autopsy, a firm adhesion, an organization of the parietal with the costal pleura, the result of inflammation, yet during life no signs were evident which would point to the existence of such trouble. This is found in phthisis, where the changes are subsequent to those in the parenchyma of the lungs, a wise provision of nature to avoid the danger of more serious accidents. It is also found under the same latent conditions where the lungs present no disease. What is the inference? Simply that a pleurisy, dry, has occasioned this condition, for it was not discovered at any time in the patient's history.

I think it may safely be inferred that a lung bound down by adhesions is not in the most favorable condition for the performance of its function; it certainly is not the original condition under which it acts in discharging its duty. Here, then, nature, ever conservative, interposes a fluid splint, separates the opposite inflamed surfaces, until the work of repair has gone on sufficiently to obviate the danger of adhesion, when the fluid is itself absorbed, and a perfect cure results. Opportune in this instance, the fluid effusion in another, owing to different casual circumstances, may, of itself, become a serious danger, because of its excessive amount. The flatness on percussion, the distant or entirely absent respiratory murmur, the increased frequency of the acts, it may be dyspnœa, either constant or paroxysmal, all tell that the working space of the respiratory apparatus is extensively encroached upon and urgently demands relief.

Simple pleural effusion, though large in amount, is usually looked upon as free from danger. Trousseau says "Pleurisy may be fatal, from the immediate effect of excessive effusion."

This tendency was well exemplified in a patient under my care a few months ago. She was twenty-four years of age, a poor woman with four children dependent upon herself for subsistence, was strong and apparently robust. In the early part of her illness she had frequently repeated chills, of short duration; there was a feeling of oppression about the chest, and the respirations were, at the same time, relatively decidedly increased in frequency; they were

about 34, with pulse 96–100, and her temperature at no time above 102° F. She was thought to be doing well under the means of treatment employed—locally various methods of counter-irritation, with such remedies, internally, as were calculated to promote absorption. The respirations continued frequent, the feeling of oppression remained, and she continued with little change in her condition, until about the end of the fifth week from the commencement of her illness, when I was hurriedly called one morning, with the statement that my patient's breathing had become very peculiar, and alarmed them much. After an unavoidably short delay, I hurried to her, just in time to see her expire. She had had a violent attack of dyspnœa, which only ended with her life. No autopsy was made, but the signs of accumulation of fluid in the right pleural cavity were unequivocal, and the amount was large.

Take *this* as the type of acute pleurisy in which paracentesis thoracis is indicated, and in which, had it been resorted to, it would have afforded a chance of saving life. Its applicability in such cases is indisputable, as the dangerous delay has shown, and it should have been early resorted to; the dyspnœa came as the herald of death, and it was then too late. Trousseau has pointed out this danger; he says, "To wait for the dyspnœa, as has been recommended, and as was formerly laid down by me as the rule, is to run the risk of allowing the time for operating to pass, and of letting the patient die, as I have done." Here pneumatic aspiration secures a positive end, that of prolonging life and of averting the imminent danger present in large serous effusions.

Where the effusion is less extensive no such danger is present, and it then becomes a more difficult matter to decide upon the propriety of this measure. These moderate effusions may be accompanied by slight general symptoms, or may be latent, or the symptoms of depression of the vital forces may be marked, the signs of a considerable amount of fluid in the pleura continue for an indefinite time, and then absorption take place, proceeding slowly, until finally, all the fluid is removed. The general symptoms, where such are marked, first improving. The extent of the flatness on percussion over the affected side, distant respiratory murmur, the displacement of neighboring viscera, all enable us to decide upon the extent of encroachment upon the lung, but what is of more importance in determining this is, the relative increase in the frequency of the respiratory acts. In a case at present under my care, a middle-aged man, the respirations at no time were above twenty-six to the minute, and pulse 96–100. Apex beat of heart felt half inch external to and one inch below the nipple. He is now in the fourth week of his illness, the general symptoms, not exceeding a feeling of depression and weakness, have all much improved; he expresses himself as feeling nearly well, the amount of effusion is lessening, the pulmonary resonance, returning in the upper portion of the chest, grows in extent each day, and at the same time the respirations grow less frequent, are now from 20–22, and his pulse 82 in the minute. With counter-irritation, rest and such internal remedies as promote absorption, this favorable course has been secured. Of the remedies used in this and another case, whose history I shall briefly narrate, the tincture of chloride of iron, highly commended by Anstie, certainly seems to have had a positive effect in promoting absorption. It was given, diluted, in ten minim doses, every three or four hours. The other case referred to was considerable serous effusion, following acute pneumonia.

Wm. McN., age 37, had been ill nine days before I saw him. He was very prostrate, delirious and restless, a small pulse, rusty sputa, and, at times, small quantities of blood were expectorated. His temperature then was 104°, F., and he was in a profuse perspiration. Hyper-resonance, or a somewhat tympanitic resonance at the apex of the right lung, and dullness extending from below to a few inches of the clavicle. Owing to his prostrate, weak condition, not much beyond this was elicited by physical examination. Respirations were 36. Bronchial breathing and increased vocal fremitus indicated conclusively the nature of the trouble. In about seven days from the time he was first seen his condition was decidedly improved. His respirations were now 26. On careful examination, flatness on percussion was found over the whole of the right side posteriorly, and over the greater portion of the same side anteriorly. Diminished movement, the liver displaced downward and the apex beat toward the left axillary line, bronchial breathing, diminished vocal resonance, posteriorly ægophony, all unequivocal signs of fluid effusion. His prostration was still evident, nevertheless he gained somewhat in strength. His temperature, it is worthy of note, assumed a somewhat curious course; for the following two weeks it was always 100° F. in the morning, and rose in the evening to 102° F. This made me, with the other symptoms present, suspect the presence of puru-

lent fluid. He had slight chills and profuse perspiration. He was taking, however, large doses of the vegetable salts of potassium, acetate, etc. A resort to a very simple manœuvre, I do not remember where I saw the suggestion, tapping with a hypodermic needle, proved the fluid to be a clear, limpid serum. Though in this case the amount of effusion was considerable, there was no dyspnœa, the respirations being relatively very slightly increased. In about four weeks the fluid began to diminish after he had made a decided progress on the road to convalescence, and now, about seven weeks from the first onset of his illness, he is almost well. The amount of effusion is very small, and does not give him the slightest inconvenience. Let us consider the points in favor of and those against a resort to pneumatic aspiration in these cases. The general symptoms improve and the effusion is absorbed. Would withdrawal of the fluid abridge the duration of illness? We may remove the fluid, but it may reaccumulate. Is there danger that the fluid may become purulent, that might be averted by removal of it? I do not think either of these questions can be answered in the affirmative. Sometimes a serous effusion is removed by aspiration, and in a few days it becomes necessary to repeat the operation, and then pus instead of serum is found, the removal of fluid stirring up a fresh activity in the morbid process, and only fuel has been added to the flame. It has been asserted that considerable effusion becomes, as time passes on, more and more filled with corpuscles, until they are at last converted into pus. That this is not so in fact, was proved by the instance in which I withdrew fluid that had remained six weeks. Only a few lymphoid cells were found, in a clear, limpid fluid. Being not certain, then, that we do not invite an increased activity of disease by interference, I think we may conclude that aspiration fills only one object, that of removing serious and dangerous compression of the lung, and further that in it we do not possess the means whereby we may limit the length of time during which effusion in the pleura may remain, and that the only proper means to be used in effusions of moderate extent, which do not directly mean danger to life, are such general ones as we may use to influence its absorption. Among these, rest is of the utmost importance, the analogy beween an inflamed joint and an inflamed pleura being striking; in the latter the rest should be as complete as possible. It seems to me, to secure this end, Dr. Roberts, in his "Practice of Medicine," has given us a valuable hint, that of firmly strapping the affected side with adhesive plaster. He says, "I have found this mode of treatment decidedly efficacious in aiding toward the removal of moderate pleuritic effusions."

Should we meet with an effusion, either originally purulent or becoming so after a time, what is the proper plan of treatment? Hectic and emaciation, with prostration, show that life is in jeopardy unless prompt and radical relief is afforded. A case I had the honor of presenting before this Association a few weeks ago will illustrate this unfortunate complication. The patient, A., a young man, 18 years of age, was taken ill in the early part of June, 1881, with what was said to be pneumonia. This was accompanied by pleurisy; after an illness of ten days or two weeks, there was a decided improvement in his condition; he, however, did not sufficiently recover to leave his room; there were some vague sensations of discomfort about his chest, which continued for six or seven weeks, when he again began to fail; he grew weaker, had irregular, repeated chills, of short duration, and was, in short, very ill. Just ten weeks after the onset of his illness I first saw him, being Aug. 14, 1881. His appearance then was such as indicated extreme prostration, marked hectic, emaciation, a frequent, small pulse, and a constant cough, accompanied by expectoration of a large amount of purulent matter, one pint a day. The latter symptom had continued for a week, during which time he was said to have failed much, the constant cough preventing sleep and causing nausea, so that he loathed the sight of food. His temperature was 102° F. On physical examination it was evident that a considerable amount of fluid, presumably purulent, occupied the right pleural cavity. A hypodermic needle proved the inference to be correct. The next day a fistulous opening was made and a drainage-tube inserted. His improvement was at once noticeable, his temperature, taken before evacuating the fluid, was 102°; in the evening of that day it was about normal. Cough disappeared, his appetite returned, and his temperature for the next three weeks remained at about normal, with the exception of one day, when a slight obstruction in the tube stopped the flow of pus, when it arose in the evening to 101 F. (the injection of dilute iodine had also been omitted). He has steadily gained in weight and has grown quite tall during this time, and may be said to be slowly improving. His temperature, taken at various times of the day during the last month, does not

show any abnormal increase. There is dullness at the apex of the affected side. Dry râles are heard. Below the spine of the scapula, posteriorly and anteriorly below the third rib, respiratory murmur, though more feeble than on the opposite side, is heard. The fistula still exists; it is found to extend almost directly backward, in a plane parallel with the horizon when he is in the upright position, and between the seventh and eighth and sixth and seventh ribs, a little external to the right nipple. A soft catheter passes in eleven inches. It is narrow, and does not hold over an ounce of fluid, which is daily injected.

In this condition the pleural cavity constitutes the walls of an abscess, and the greatest hope of recovery exists in this radical measure; by it we obtain free exit for the contained matter and secure drainage. The cure is effected by granulations. Cicatricial tissue is developed, upon the contraction of which depends the retraction of the sides of the chest, which is shown to be due to an active force, and not, as was formerly supposed, to the passive influence of atmospheric pressure, which, being equal on both sides, is incapable of producing any such results.

In this connection it is of interest to quote the tabular analysis of Goodheart, Guy's Hospital Reports, 1877, given by Martindale (*American Journal of Medical Sciences*, "Empyema," July, 1881). It includes seventy-seven cases. In fifteen no treatment was used; there were two recoveries, both children; eleven pointed and discharged; there were two recoveries. The remainder, by the radical method, got well (incision and drainage tube). These, with my case, should certainly leave no doubt as to the relative advantages of a radical method of relief, as compared with any temporary means of relief that we may use instead.

THE NEW YORK CODE.

BY DR. R. C. M'EWEN, M.D.,*
Of Saratoga, N. Y.

Old things are passing away, and we are called to a newer life, in the adoption of a more liberal gospel; the professional spirit, so long hampered by the hidebound restrictions of a primitive ethical code, is to become regenerate, and the broad banner of legal enactment is raised as the standard of scientific qualification. The new code of medical ethics adopted by the Medical Society of the State of New York is now the subject of discussion within and without the profession. To the laity, who regard the science of medicine as founded upon some particular dogma, and each individual practitioner as the representative of a system, its liberality is hailed as evidence of advance, and we are considered to have broken the fetters that bound us; to have laid aside the bigotry and intolerance that paid so little deference to the more modern scientific methods, and, at last, to have granted them the recognition they deserve. The secular press has expressed its unqualified approbation, and the editorial pen pictured, in glowing terms, the benefit to all mankind that shall flow from the decease of an antiquated form, and the birth of a spirit more in accord with the liberal idea of the age, and the toleration that should characterize a truly progressive, scientific spirit.

The *new departure* is held up to professional favor by but a small portion of the medical journals of the country. Its champion is the *Medical Record*, of New York, a prominent journal at the reputed birthplace of this liberal doctrine, and, editorially, it has set forth its satisfaction with the independence of the position, and its expectation of the coming day when those who now see through a glass darkly will accord the honor due the pioneers in so magnanimous and so radical a reform.

But from the medical press at large and the profession itself, from Maine to California, comes forth an earnest protest against the action of our State Society, and a demand that at the coming meeting of the American Medical Association the profession shall make known its position by the exclusion of the delegates from our State Society from that body, by a repudiation of the leveling doctrines of the new laid code, and a re-assertion of continued adherence to the faith of our fathers, rather than recognize the claims of pseudo-science to equality of position; rather than accord to imposition the genuineness of truth, or raise the traders in a name to the level of honest and sincere representatives of scientific progress. The act of the State Society is a repudiation of a governing principle of the national body, and a departure, in the name of tolerance, from a wise conservatism that is opposed to professional affiliation with irregular practitioners. It gives to State law the precedence in determining who shall be recognized as entitled to practice, and admits the legally qualified (if such there be) to all that has been accorded the educated physician. It is a denial of all that scientific medicine has claimed for itself in the rejection of so-called systems of practice, and bows, in a spirit of mock sentimentality, to

* An address delivered before the Saratoga County Medical Society, by the President.

the fictions of science, apparently sustaining a fraud in order to pocket a fee. The action of our national body is looked forward to with anxiety, and we wait to learn whether the old and tried shall have passed away and we are to be left to the disintegration that will follow the new. For the old we do not claim perfection, but better that, with its conservative and protective barriers, than the chaos of so liberal a departure from all restrictive influence. It is claimed that the new-made code is begotten in the interest of the specialist, who, in the name of progressive liberality, seeks to enlarge the borders of his usefulness and the contents of his pocket-book; that it was passed by but a minority of the members of the State Society, and is in defiance of the wishes of the majority. If so, let it be repealed at the annual meeting in February next, and the seal of disapproval be placed upon the act of a minority who seek to honor the representatives of a scientific fiction, in order that they may promote individual interest. It is idle to discuss the question of benefit to mankind from consultations with irregular practitioners.

The patient, in his critical condition, cares not a fig for the refinements of pathology, or a professional agreement on questions of diagnosis. The differences between the claims of scientific medicine and the dogmas of the day are not to be reconciled while the patient waits, and the impassable gulf between the true and the false is not to be closed by a shaking of hands over the chasm, in the interest of a suffering humanity. The physician of the so-called *regular* profession is classified as belonging to the old school. Ethics and therapeutics are more particularly held up to adverse criticism, the one interfering with a liberality hailed as evidence of progress, the other considered as weighed down by the dust of age, and founded upon principles that will not bear the test of rational examination. That defects exist in the code, which disturb our relations to the so-called modern medicine, and that it demands revision and readaptation, may be conceded. But in what respect can the claim be sustained that the science of medicine of to day is in any sense a theory of the dead past, or that its principles rest upon foundations that have been superseded by newer light in the dilutions of infinitessimalism. We are reaching forth, from day to day, to better things, and walk in the light of new developments. The hand of science points to new discoveries, that are as strange in the medical world as are those in other branches of scientific pursuit. But they are not born of dogmas, they owe no allegiance to "similia similibus" or "contraria contrariis," and reflect no tenet of sect or practice of schools. They stand on the broad basis of inductive science, and are the rounds of the scientific ladder upon which we rest, reaching out toward further development and greater practical results for the benefit of mankind.

A knowledge of anatomy was essential to progressive medicine, and the history of its rise and development, is coincident with more scientific modes of thought and study. Physiological investigation followed the better knowledge of form and structural arrangement, and the light shed upon the vital processes through physiological anatomy, enabled the pathologist to understand more clearly the changes in intimate structure incident to the various departures from normal condition that constitute disease.

The history of medical science, as it portrays the brilliant labors of the past, presents a page that brightens with each advancing age. We treasure up the heritage left us. The ties of tradition are not severed, but new horizons are opened up to our view, and in the light of the past we search for further knowledge from the standpoint of the present. By way of illustration, let me point you to the experiments of Pasteur, and their bearing upon the germ theory of disease. That we are surrounded by invisible germs, capable, under favoring circumstances, of producing disease and death, is no longer a theoretical view of our pathological relations. The mode and manner of their production in the animal and vegetable world, the laws which govern their vitality, the circumstances which modify the intensity of their action, and the relation various forms bear one to the other, are still subjects of investigation.

As remarkable as any of the developments recently brought forward are those set forth in the paper recently read by Dr. Koch, before the Physiological Society at Berlin, claiming to have discovered a specific germ as the cause of pulmonary tuberculosis. He endeavors to prove the truth of his views by the test of inoculation with a ferment containing the germ or bacillus tuberculosis, and as a result of such experimentation asserts the contagious and infectious nature of the disease. What a departure is this from the theory of blood dyscrasia and the deposition of gray tubercular matter, as set forth by the German pathologists, from the caseous degeneration of Niemeyer, or the more recent view of catarrhal inflammation, with its infecting foci of disease in a subject already scrofulous. We have mentioned these

investigations in illustration of that spirit abroad in the science of medicine seeking to know and develop the things that lie beyond the horizon that now limits our view. A spirit that pervades and leavens the professional body, raising it above the isms and pathies of the day, pointing us backward to the landmarks of scientific investigation that were progressive steps in the past, giving us the practical certainties of to-day, surer foundation stones than the innovations of so-called modern scientific medicine.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

NIGHT TERRORS OF CHILDREN; RENAL CALCULUS; PYELITIS.

Gentlemen:—The first case that I shall show you to-day is this little boy. I do not know his history, but I shall ask the father a few questions, and you can note the answers.

He is three years old; the third of four children; the others are living and healthy; the father and mother are healthy; the mother is somewhat nervous; the child was healthy when born; neither this child nor the others were nursed at the breast; the child grew well but did not develop rapidly; he was twenty-two months old before the teeth began to appear, and he still lacks one. Examining the mouth, I see that the teeth are well developed but rather peculiar in shape, showing a want of development of one lobe of some of the teeth. This affects chiefly the molars, which are curiously shaped and pointed. The lower right lateral incisor has never appeared. His dentition, then, has been singularly irregular, retarded, and is still imperfect. In other respects he looks like a sturdy child. The head shows no signs of rickets nor of hydrocephalus. The features are well developed. He eats well. The bowels are now regular. During his first and second summer he had sharp attacks of cholera infantum. The abdomen is somewhat prominent. The abdominal walls are quite fat. There is no enlargement of the liver nor of the spleen. There is no distention of the abdominal veins, but there is an unusually thick deposit of fat for so young a child. A great deal of the prominence of the abdomen depends upon this fat, while there is only that degree of distention of the intestine depending on the imperfect development of the muscular layer of the intestinal wall, that we constantly meet with. You frequently see bellies as large as this in children who have been disposed to diarrhœal trouble during dentition.

Recently we have had nerve symptoms developing. He first began to have nervous attacks four weeks ago. The father states that he was awakened at midnight by his wife, and found the child rolling its eyes, and also noticed some contortion of the body. There seemed to be some unconsciousness, for the child did not reply to the questions put to him. He soon came to, and then went into another attack of the same character. This lasted for two or three hours, and finally stopped after the child's feet had been soaked in strong mustard water. In one of these attacks he cried out, "See there! there! there!" and in moving around he caught hold of his father's hand, and immediately began to cry and scream, as though he had touched the dreaded object. He has had two of these night attacks. The last one did not last as long as the first.

In addition to the night spells the boy has had day terrors; that is, he will, while playing, quit his play, run to his mother, seem frightened, and say that something is after him. He never says what it is, excepting at the last spell, when he said that there was a man up stairs who was going to hurt him. At these times he does not work his body, and the parents do not notice anything strange about his appearance. He does not seem to lose consciousness. He does not cry out. When his mother reassures him, the spell soon passes away, and he returns to his play. The railroad runs a short distance from the house, but the father thinks that the child was never frightened by the locomotive, nor in any other way. Once, when a train went by, he said that it was going to run over him.

This is an unusual case. You are probably all familiar with what are termed night terrors in children. They are spoken of as night horrors, and as nightmare. The best term is night terrors, which explains them exactly. They are most common in children, but I have known them to extend beyond childhood, even into adult life, but I have never known them to come on in adults who had not, as children, suffered from the disease. Although they occcur most frequently during the night, they may also occur during the day. Their characters are rather uniform. I shall describe the commonest sort. A child who has apparently been well, but perhaps a little irritable and peevish, is put to bed and goes to sleep as usual, but wakes up in the earlier part of the night, say about ten or eleven o'clock. Generally the first thing that attracts attention are cries, incoherent screams and strong expressions of terror from the child's sleeping room. On running there, the child is found, nearly always, in some unnatural position, rarely lying still, but sitting up, or standing, looking very much frightened, holding itself in a strained attitude, screaming, sometimes incoherently, but at other times with a definite purpose, as; "Take that big black dog away!" or "That snake is going to sting me!" or "That man has a knife to cut me!" and the like; or the child may simply cry and scream, evidently in great terror, but without any coherent purpose. You call the child and shake him, but it produces no effect. The child is beyond the reach of reason, and does not seem to hear. Often the eyes are wide open and staring, but you cannot attract the child's attention. Holding the child seems to increase the terror, the child thinking that the

dreaded object has seized him, thus showing complete want of recognition of the nurse or parents. After a few moments, simply seeing that the child does not hurt himself, speaking gently, without touching him, the child begins to take long breaths, and very often says that there is nothing the matter, throws himself down, and almost immediately goes to sleep. Others will, after they come to, say "Where am I?" be somewhat nervous, but with a little soothing, lie down and soon go to sleep. There is not usually a second attack during the same night, but there is apt to be a recurrence of the attack at longer or shorter intervals.

I have seen attacks similar to this take place in the daytime. I remember a case that I saw last September, during the very hot weather. A child, eight or nine years old, of delicate nervous organization, and precocious intellectual development, rather frail, who had been subject to gastric catarrh, with frequent vomiting, lasting for several years, and for whom it had been found difficult to select a suitable diet, had been sent to the seashore. On the trip home she seemed excitable and nervous, talked incoherently, and seemed greatly afraid that an accident might occur. Reaching this city, she was taken to her residence, and very soon she suddenly went into a state of uncontrollable terror. I saw her a short time afterwards. Her body was bathed with sweat, she had torn off most of her clothing, she was trembling violently, and it was with great difficulty that she could be restrained from throwing herself on the floor. When the paroxysms would come on, she would exhibit great dread that a large dog would bite her. Some time previously she had been much interested in a large dog. At these times it was almost impossible for me or her father to hold her. She would tear the clothes from herself and those who held her. During these spells she seemed entirely inaccessible to calls, persuasion, or soothing. These attacks, under the influence of remedies and soothing treatment, gradually diminished, and on the following day she was herself again. I had never before seen as bad a case of day terrors, associated with prolonged hallucinations and delirious spasms, as the one I have described, but I have seen a number of cases where the terror occurred during the day. These attacks you will find, for the most part, connected with derangement of the digestion, and an over-sensitive, nervous system. You will ordinarily find them occurring in children with an excitable state of the nervous system, derived from the parents, or due to the depressing effects of severe illness or defective nutrition. In addition to the state of the nervous system we have, as a rule, local irritation, for the most part connected with the gastro-intestinal canal. Overeating, or an indigestible meal, will bring on night terrors in a child so disposed. So, in the case of which I have spoken, there had been a long continued gastric derangement, and the diet had not been properly regulated. Irritation of the genito-urinary canal may bring on an attack, and some times they come on after some excitement, fatigue, application to study, and the like.

These attacks are in some cases analogous to one of the types of hysteria. In other cases they are analogous to epileptiform seizures. There is considerable irregular muscular movement, and, for a moment, there is a form of unconsciouness. The attack passes over and the child sinks into a deep sleep. There is not the frothing at the mouth, the biting of the tongue, nor the true convulsive movements, *i. e.*, incoherent involuntary contraction of the muscles, that we see in true epilepsy, but I have said enough to indicate the analogy.

With this much as a preface, you will, in reference to the present case, see how difficult it is to define the nature of the attacks. For instance, the day attacks are very peculiar. They seem to be the result of some fright that this child has had. It is not improbable that the child has been frightened by the cars or the loud blowing of the whistle. Of course, if the child had been of a vigorous nature this would have had no effect. The terror may often be produced by excitement in playing, or by fatigue, or by reflex irritation from overloading the stomach, or by injudicious food.

We might think that these day attacks were attacks of petit mal. Lesser epilepsy sometimes takes this form. There is in this disease an instantaneous, giddy, disagreeable feeling, the person grasps something or lies down, draws a few breaths, and the attack passes over. If such a spell occurred in a child we can easily understand that it would cause a feeling of terror in the child, it would run to its mother, and by that time be apparently well. It is, therefore, doubtful, I think, whether these are attacks of terror or attacks of petit mal. The nocturnal attacks much more simulate a modification of epilepsy than ordinary night terrors. This child goes to bed and awakes with a scream. On going to him he is found in a somewhat convulsive state, with momentary unconsciousness. A convulsive condition of the muscles is not common in night terror. This child passes from one attack to another, each spell closely simulating the previous one. On the first occasion they lasted for several hours. During these attacks the child seems to be very much frightened.

I think that it is possible to explain the night seizures as attacks of night terrors, although exhibiting unusual features, and the day attacks may be peculiar expressions of some condition of over sensitiveness of the nervous system, with past frights in which very trifling causes bring on momentary terror.

As to the Treatment.—The tongue is moist and coated. The bowels are somewhat irregular. He sleeps well. His diet consists principally of bread, butter, soft-boiled eggs, and weak coffee. It is now two weeks since the last night attack. During the last ten days he has had only one day attack. Previous to that he had them every day. I should, in the treatment of this case, first endeavor to regulate the diet. I should not give coffee under any circumstances, but urge the child to take milk diluted with an equal quantity of water; I should allow him a soft-boiled egg, once a day, meat, roast potatoes, fine grits, bread and butter, and milk and water.

Direct Medication.—I think, taking the history in connection with the symptoms, that we have

had, undoubtedly, a long continued irritation of the stomach and bowels, an exaggerated sensibility of the nervous system, and from some cause, a defective state of nutrition, a defective developmental power. I should give him a teaspoonful of the emulsion of cod-liver oil and hyposulphites after meals. I should then use one of two sorts of remedies. Either remedies directed to the nervous system, and of these, I should select one of two, either the bromides by the mouth, or quinine and assafœtida by the rectum. I should give a suppository containing—

Quinia sulphatis
Assafœtida āā gr. iss.

or, if this irritated the bowel, it would have to be omitted, and I should give—

Potassii bromidi
Sodii bromidi āā gr. iss.

in a little calisaya elixir, three times a day, between meals, or, in the second place, if I found, under close observation, that this child's digestion was not right, that the stools were broken, irregular in color, and imperfectly digested, and that there was a good deal of flatulent distention of the bowel, I should not give the remedies of which I have spoken, unless, perhaps, a little quinine and assafœtida at night, but I should give remedies directed to the mucous membrane of the stomach and bowels. These would be either pepsin and bismuth, or oxide of silver. This is the class of cases, either of spasmodic nervous trouble or of epilepsy associated with gastro-intestinal irritability, where the salts of silver have earned their reputation; nitrate of silver is considered by the laity as one of the most reliable remedies in the treatment of epilepsy. Nearly all the cases, if not all, that have been cured by this drug, have been cases in which the attacks have been reflex from irritation of the gastro-intestinal mucous membrane. If this child, on careful examination, presents evidences of a long-continued subacute irritation of the stomach and bowels, I should give from one-twelfth to one-eighth of a grain of oxide of silver in a small pill, or else one-twenty-fourth grain of nitrate of silver in solution. With this I should give the cod-liver oil, regulate the diet, keep him where he would not be frightened by the cars, and be very careful that he did not get over-fatigued or excited.

Renal Calculus, Pyelitis.

Our next patient gives us the following history: He is 42 years old. His parents are dead. One died of dropsy. He has never passed a stone. Five years ago he noticed a sudden attack of pain, which began over the right kidney. Since then he has had a good deal of pain over the kidney, and more or less pain running into the bladder and genital organs. He first noticed a change in the urine three or four days after the first attack. There were a few spots of blood, and there has been, occasionally, a little blood since.

Cases of this kind are so common that it will repay us to give a good deal of careful study to them. There are some very curious features about them, in their symptomatology, course, and the results of treatment, to which I shall call your attention.

The first question to decide is whether this man is suffering from a disease of the bladder or of the kidney. The man tells us that he has a good deal of pain around the kidney and down into the bladder, and that he finds a thick, white sediment in his urine, and sometimes a little blood. These are symptoms which are met with in disease of the bladder and in a certain kind of disease of the kidney. The disease of the kidney is not that which we call Bright's disease in any of its varieties, but it is a chronic inflammation of the pelvis of the kidney and upper portion of the ureter; in other words, pyelitis. It is the same sort of disease as cystitis, *i. e.*, an inflammation of a mucous membrane. We proceed, then, to ask ourselves: Where is the seat of this mucous inflammation? Is it in the bladder or is it higher up in the urinary passages? The elements upon which you will base your diagnosis are chiefly, (1) the seat and character of the pain; (2) the evidences of the presence or absence of irritability of the bladder; and (3) the chemical and microscopical characteristics of the urine.

The Seat and Character of the Pain.—In cystitis there is a great deal of burning and tenderness about the vesical region, and from time to time, when the disease is aggravated, there is aching extending up toward the kidney. In pyelitis, on the other hand, the pain, with great constancy, is found in the renal region, and extends often along the course of the ureter into the bladder and groin, attended with drawing up of the testicle and pain in the end of the penis. The retraction of the testicle and pain in the penis are not so constant as the location of the pain in the renal region, and its tendency to extend along the ureter. In addition to this there is, in the intervals between the sharp attacks of pain, dull, deep-seated pain over the kidney and tenderness on pressure, so that if we direct the patient to lean forward and press over the kidney, we find, on one side or the other, decided soreness. Often you will find that any sudden jar to the patient's body will give him pain in the renal region. The amount of pain will be governed, in the first place, by the severity of the inflammation and by the irritability of the parts, and secondly, it is governed very much by the presence or absence of a calculus in the pelvis of the kidney. If there is but one smooth stone, imbedded firmly, there may be very little pain, but if the stone is jagged and free to move, the slightest jar will cause extreme pain.

You will gather from this that the seat and character of the pain, the presence of renal tenderness, and the comparatively slight amount of pain over the bladder, will cause you to think that it is the pelvis of the kidney that furnishes the pus, and not the lining membrane of the bladder.

In regard to the urine. I here show you a sample of it. It contains a thick, white sediment, which, on shaking, diffuses itself through the liquid. This shows that it is pus. Mucus, on agitation, forms little masses, which float around in the urine, but it does not break up and

diffuse itself, like pus. This urine is albuminous, loaded with pus, contains amorphous phosphates, some urates, but no tube casts. In cystitis the urine is apt to be fetid, and the deposit nearly always consists largely of stringy, ropy mucus, and on microscopic examination we find a great deal of mucus with a moderate amount of pus. In pyelitis there is little or no mucus but a great deal of pus.

The most frequent cause of pyelitis is the formation of a calculus. It may also be caused by repeated chillings of the surface and the establishment of catarrhal pyelitis. This latter cause is more apt to give rise to cystitis. If only one kidney is affected the cause is probably a local one.

While the symptoms to which I have referred are the common signs of calculous pyelitis, there are other symptoms which I have noticed in some cases, and which are very misleading. I remember a case which occurred several years ago. A man of gouty diathesis and intemperate habits was seized with a headache which continued without the slightest intermission until his death. Nothing relieved it. There were no symptoms of organic disease of the brain. There was no syphilitic nor malarial history. No toxic poisoning of any kind. He was tried with large doses of quinine, large doses of arsenic, with the iodides and the bromides, codeia, aconitia, gelsemium, counter-irritation of the most severe type, localized galvanism of the brain, change of scene, with every influence that could be brought to bear, but the pain continued without change until he at last sought relief in morphia. From the occurrence of the headache until his death he had not an instant's ease, except when under the influence of morphia. After death, the most minute examination of the brain was made, but there was nothing found but a little thickening of the dura mater. In the kidney there were found twelve or fifteen calculi imbedded in its surface. I never knew whether they had anything to do with the pain or not, but that was the only lesion found in this man's body, who had suffered from the most severe headache for four months. There was no pyelitis.

The other day I saw a case in which there was a floating kidney, containing a calculus. The woman had complained of vomiting, and not rarely vomiting streaked with blood, and progressive emaciation. Cancer of the stomach had been diagnosed. At the autopsy, the stomach was found to be normal, and the only lesion was the renal calculus in the displaced kidney.

Occasionally you will find a hectic irritation kept up in these cases. There may be remittent or intermittent febrile paroxysms, with night sweats, progressive anæmia and emaciation, simulating the condition which we find in deep-seated abscesses. This is caused partly by surface irritation, and partly by the presence of some septic material in the blood. You find in these cases a great dissimilarity, both in the general and in the local symptoms. Sometimes the local symptoms are very marked, at other times these are very much in abeyance, and the reflex symptoms are very prominent.

Given, then, a case of pyelitis, we desire to know whether or not there is a calculus. It is often difficult and sometimes impossible to determine this with any degree of certainty. I would say that we determine this, chiefly, by the amount and extent of tenderness, the amount of pain following agitation of the body, and the frequency with which the urine is blood-stained, or contains macerated blood corpuscles. When there is a calculus, a little blood is apt to be passed. It is macerated by remaining in the urine, and the microscope reveals the altered character of the blood corpuscles, showing that they have not come recently from the bladder. It is not discharged in clots, as in cystitis. It sometimes gives a light pinkish hue to the urine, but at other times it does not color it at all.

Our treatment is governed by these considerations: whether there is or is not a calculus, by the severity of the local inflammation, and by the character of the general symptoms. If there is clearly a calculus, and we have waited for some time, but there is no sign of its coming away, and the symptoms are very urgent, it is impossible to avoid considering the question of cutting down on the kidney and removing the calculus. These are the cases in which nephrotomy is earning a just position for itself among surgical procedures. A large number of cases have been operated on, with an encouraging proportion of successes.

Can we do anything to favor a solution of the calculus? I doubt if there is any form of mineral water, or any remedy, that can lessen the size of the stone. The only way in which this could be done would be indirectly, by favoring a healthier state of the mucous membrane of the pelvis.

Rest is, unquestionably, one of the most important elements in the treatment. This may, with advantage, be absolute, for a considerable period. There is no harm in keeping such a patient in bed for several months. Secondly, whether this is done, or not, a most rigid attention to hygiene and an avoidance of those little exposures which are apt to favor catarrhal attacks are necessary. In the next place, the diet requires close attention. It should be simple and unirritating. One which neither contains such substances as are irritating to the kidney, as alcohol, highly flavored dishes, articles containing spices, and the like, nor, on the other hand, articles which load the urine with a great deal of organic matter, as very rich, sweet and heavy dishes. It should be one which will promote the free secretion of urine.

Unquestionably, a milk diet is, on the whole, the best. It is desirable to place such patients upon a diet of milk, whey, a little farinaceous food, and a little animal food, as eggs, and tender, lean meat. Rest, rigid diet and hygiene put the patient in a very favorable condition for having this inflammation healed.

Besides this there are drugs which undoubtedly exert a beneficial influence upon this membrane. In the first place, those drugs which keep the urine neutral or slightly alkaline, and promote a free secretion of urine, are useful. For this purpose we may employ many of the saline mineral waters. As a type of this class I may mention Vichy water. This is an agreeable, powerfully alkaline, and very unirritating water.

Then there are waters which are alkaline and chalybeate. These are exceedingly valuable. If Vichy water is used, you may give iron associated with it; or you may give iron in combination with an alkali, as, for instance, a vegetable salt of iron, with potash; or Basham's mixture may be employed.

There are other drugs, the so called alterative diuretics, which have a beneficial action upon the urinary organs; thus, uva ursi, buchu, copaiba and sandal wood, may be mentioned as examples of substances which, taken into the stomach and absorbed, are excreted by the kidney, and thus mix with the urine, forming a slightly stimulating solution, which bathes, day and night, the irritated surface. Thus, in a case where there is not much urgency, and where the simple hygienic tonic course does not relieve the discharge of pus, it is proper to associate one of these alterative diuretics, and they may modify favorably the inflammation of the mucous membrane.

Anything which modifies the character of the urine and allays the irritation, reduces the amount of pus and lessens the deposit of organic matters and urinary salts upon the calculus, and therefore, under the slow action of the urine, the stone may be gradually worn away until it is small enough to be discharged, so that, indirectly, this treatment may lessen the size of the calculi. I have seen this occur not rarely.

More commonly another result takes place. The irritation and the amount of pus may diminish, the calculus still remains, but adhesions have formed, and it becomes encapsuled. It may block up the openings of one or more tubes, leading to cystic degeneration of the kidney, or it may lie in such a position as to offer no impediment to the passage of the urine.

Lastly, the stone may remain almost indefinitely, and the patient enjoy fair general health, as long as he pursues a very careful hygienic course. A certain amount of pyelitis persists, the urine always contains a little pus, a slight cystic irritation remains, and the patient, on the least indiscretion, is warned of his danger by an attack of colic.

In this patient we have reason to suspect a calculus, but the symptoms are mild. I shall put him on the treatment which I have described, and shall continue it for several months.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

Do Mammary Adenomata Undergo Carcinomatous Degeneration?

BY HENRY BEATES, JR., M.D.

Mr. President and Members:—This type of neoplasm is still spoken of, by representative continental pathologists, in a manner which clouds the mind with erroneous conceptions, and it is with the intention, so far as my experience and observations enable, to clearly describe and consider the clinical and pathological phenomena of the tumor, that I present the subject for your consideration. The title is selected because it gives prominence to a vital point in the history of these growths, and also that an opportunity has recently been afforded me to conclusively determine the affirmative of the mooted question. The consideration of the many neoplasms classified as adenomata or prefixed with the name adeno —— ——, will here be omitted, as our works of reference sufficiently abound with the confusing literature of the subject. Billroth, Green, Cornil and Ranvier, Wagner, Paget and others, refer briefly to mammary adenoma, and while assigning to it identity, emphasize the fact (?) of its great rarity. The accumulated statistics of many surgeons, for years, afford us a history of but fourteen cases, and were these typical tumors, alone, admitted to have occurred, we would certainly have to deal with a most extremely rare growth. That the tumor is comparatively rare cannot be gainsaid, but that it is of far more frequent occurrence than statistics indicate is certainly a fact. Many mammary tumors, microscopically determined to have been adeno-myxoma, adeno-fibroma, adeno sarcoma, etc., etc., will, I think, by future experience and study, prove to be either adenomata, undergoing these secondary changes, or true primary myxomata, fibromata, etc., etc., developing, as this type of neoplasm does, from the connective tissue of the gland, and permeating the true adenoid structure and separating the acini in such a manner as to present appearances sufficiently misleading to occasion errors in diagnosis. Note here, that these compound neoplasms are composed, histologically, of true gland structure plus connective tissue new formation, and that there is a broad difference between these and carcinomata, which develop from epithelial structure alone.

In this connection it may be proper to refer to a form of tumor, or more correctly speaking, lumps, which occur in the breasts of ladies in active catamenial life, that in no sense constitute adenomata, although requiring close observation and care lest they might, by irritation or injury, eventually become morbid. Reference is made to those instances, certainly of frequent occurrence in the experience of every practitioner, of lumps that are located in segments of the mammary gland, which, upon examination, are found to be enlargements of one or more lobules, due to either stenosis of efferent ducts, congestive thickenings, etc., and which during menstruation become markedly increased in size, hyper-sensitive, and even painful. These enlargements are of irregular contour, capable of being freely grasped, and when lifted elevate the whole gland, demonstrating clearly that they are of the gland itself. Comparison with the unaffected side gives no evidence of hyperplasia. The difference of sensation imparted by these and true adenomata can only be interpreted by comparison, for it must not be forgotten that the true neoplasm is a new formation of the gland itself, and when grasped and lifted also elevates the whole breast. The evident attachment by a pedicle is a point for differentiation. That many of these lumps have existed and after the menopause disappeared is a truism needing no demonstration. That

many tumors presenting almost the same phenomena as the above have existed, and at the menopause not disappeared, is also true. That the former variety of lump has been recognized and known to disappear, and confounded with the true neoplasm, is a sufficient explanation of the indecision of the profession regarding the treatment. Many instances are called to the minds of all, of tumors, very vaguely called, and as indefinitely diagnosed, that have been removed, returned, or not, some successfully, others with fatal consequences, and we have formed conclusions pro and con, unconsciously regarding them as confirmations of opinions which, when analyzed, shine with inconsistency and ignorance.

What a degree of doubt burdens our minds when forming a diagnosis and recommending a plan of treatment! How we await the time when unequivocal manifestations of malignancy occur, to confirm a dread, or if perchance it may happen, disappear, and relieve us of further responsibility! What visions of cancer return, metastases, etc., cause us to hesitate, yet opposed with an indefinite recognition, that conservative treatment may find us off guard and surprised with malignancy, which, if it had been properly treated, would have saved our patients, harass our minds, and attest the ignorance of this subject! Because Mrs. A. had a breast tumor for 20 or 30 years, that disappeared at the menopause; Mrs. B. one of 10 years' duration, that was removed and has remained perfectly well for 20 years, shall we tell Mrs. C. that her's, so far as our senses enable us to determine, is identical, and that as Mrs. A.'s vanished and Mrs. B.'s did not return, and was, therefore, not cancerous, it would be folly for her to undergo the risks of a surgical operation? This might be done if we knew that adenomata did not become carcinomatous, and were certain of a correct diagnosis, for it must not be forgotten that the nature of the tumor present is very frequently not understood. A thorough knowledge of the histology, clinical history and pathology of adenoma will clear many doubts, enable an unbiased opinion to be formed, and a proper plan of treatment advised. As the affirmative of the question is herein maintained, and per consequence, the extirpation of the breast advised, attention is invited to the histology of typical adenoma, in order to secure just approval or condemnation. This rough diagram illustrates sufficiently clearly the structure of the normal gland.

Special points noticeable are, first, the small proportion that the connective tissue bear to the acini; second, the few fusiform cells in the wall of each acinus and interlying connective tissue; third, the almost uniform size of acini; fourth, the membrana propria, which is the true basement membrane, upon which are situated the epithelial cells, which constitute the fifth object of notice; these cells are somewhat columnar, bear a constant relationship of breadth to height, and possess nuclei; sixth, spaces between the acini, which seem to be separations of the interacinous connective tissue, that are lymph channels, and serve an important factor in carcinomatous changes, as the proliferated cells congregate here, and thence are conveyed through the vessels (lymph) to the contiguous glands. The epithelium constitutes the secretive element, and elaborates from the blood, the lacteal fluid. The gland is in full sympathy with the reproductive system, and during the catamenia becomes hyperæsthetic and even painful. This is due to hyperæmia, and is of interest, in so far as the general belief, that when more blood exists, then do we have excessive development, is concerned, and the possible etiological factors thus suggested.

This describes the appearances presented by the section under the microscope, of pure adenoma. The only difference consists in an increased proportion of connective tissue, and a greater number of fusiform cells. A greater tendency to formation of fibroid tissue is seen. The lumen of each acinus is seen to be occupied with epithelial cells, such as we presume to be the fact in a gland secreting milk. The only difference here, however, being the freedom from fatty elements. Notice especially that the membrana propria is intact, and that the lymph spaces are empty.

Comparison of this with the former demonstrates vast histological differences. The connective tissue is increased, the fusiform elements more numerous, and lymphoid cells infiltrate the whole structure. The lymph spaces and vessels are distended with large, multinucleated, irregularly shaped, epithelial cells. The membrana propria is destroyed, and can only be recognized in portions of some few acini.

In a normal lymphatic gland nothing is discernible but a field of lymphoid cells partitioned into small, circular areas by a delicate fibroid stroma. These glands, when the seat of carcinomatous changes, present a typical appearance of malignant cancer, which, as you know, consists of stroma made up of fibroid structure arranged in bands joining, at acute angles, with the spaces thus formed, filled with epithelial cells of irregular shape, multinucleated and aggregated. This is represented by the next diagram, and can be recognized by the slide under the microscope.

This gives a fair representation, and clearly demonstrates the vast change that occurs in malignant degeneration. The transformation is so complete that, were it not known to be a section of lymphatic gland, it would be impossible to state whence the specimen was derived. The section you are viewing is taken from an axillary lymphatic gland. The history of the case will be given later. The adenoma is shown to offset the general belief concerning the "extreme rarity" of their occurrence and that the changes above referred to may be seen and recognized by all.

The history of this case, diagram No. 2, is as follows: Mrs. B., aged 49, married, nulliparous, has always enjoyed excellent health until three years ago (four after the menopause), when she first discovered a lump occupying the outer and lower two-thirds of the right breast. This was not painful, and remained about the same size until ten months before relief was sought. At that time a pain, lancinating in character and aggravated nocturnally, developed and slowly became more severe and exhausting. The tumor increased rapidly in dimensions, and the

nipple discharged a lacteal fluid. Four months later the unaffected gland began to secrete a similar fluid, although nothing could be detected by touch. The intense pain prevented sleep and impaired appetite, and produced marked failure of flesh and strength. The patient was first seen at this period. I found the tumor hard, movable, exquisitely painful and faintly irregular in contour. The cutaneous surface was not altered in appearance, and not attached. Nipple retracted, exuding the above mentioned fluid in sufficient quantity to soil the garments. Axillary glands free.

Extirpation was advised, and four weeks later effected. I removed the whole gland and adjacent adipose tissue. Patient is now well, enjoys excellent health, and seven months since removal presents no manifestations of return. (Adenomata, when removed without including gland, are prone to return.)

The patient from whom diagrams 3 and 5 are sketched is under the care of Dr. Parrish, who presented the specimen to the Philadelphia Obstetrical Society with the following history. The tumor was referred to me for microscopical examination. Lady, Mrs. Blank, aged 69, mother of several children, first noticed a lump in her breast 31 years ago. It was small and very hard, slightly irregular in contour, free to be moved, and painless. For 30 years it occasioned no trouble, but during the 31st year became painful and began to enlarge. The axillary lymphatic gland also became enlarged and indurated, and subsequently proved troublesome, from nocturnal pain. The skin over the tumor became attached, but no other changes were noticed. Excision was effected, and the results you have before you. No hereditary tendency to carcinoma exists in her family.

Having seen these facts, and being able to verify them by personal observation, to what other conclusion can we arrive than that adenoma of the mammary gland does become carcinomatous? Can the objection be raised that this tumor was always carcinomatous? The whole clinical history of carcinoma, in all its forms, and under all circumstances, stands prominently in opposition, and does not, for one moment, permit of such a supposition. We are forced, then, to conclude that this instance, at least, conclusively demonstrates that it, originally a pure adenoma, has, after many years, become the seat of carcinomatous degeneration, and constituted the point from which the axillary glands, and probably whole system, became secondarily involved.

Mammary adenoma is peculiar in that it affects primarily but a segment of the gland. Its growth is, as a rule, slow, varying from one to thirty years. Exceptionally it may be fully developed in a few months. Its shape and contour closely resemble scirrhus and other forms of carcinoma, and from these conditions offers no means of differentiation. The pain and retraction of nipple occurs in this as in cancer. When adenoma occurs during the child-bearing period a marked molimenial exacerbation of subjective symptoms occurs, which affords a good diagnostic picture. The often detectable pedicle existing between the neoplasm and the gland proper affords additional evidence of its nature, as well as the secretion of lacteal fluid, even if in nullipara.

The involvement of skin, enlarged vessels and lymphatics, is not seen until carcinomatous change has occurred. Regarding treatment, but little can be said. The tendency to return of the pure neoplasm, which, in its non-cancerous state, occasions severe suffering and may prove fatal, demands removal, not of the tumor alone, but the whole breast. The fact that it may become cancerous more urgently demands a similar course, and that *early* in its existence.

Remarks.—Dr. L. Brewer Hall believes that carcinoma may afflict any portion of the system, and especially morbid and cicatricial tissues. It may follow a bruise, or even a scratch. Such being the case, it is not impossible for adenoma to become cancerous, yet is it so liable so to do as to warrant operation before manifestations of degeneration occur? If the growth remains stationary, I would be disposed not to interfere and await further developments. The clinical behavior should suggest the treatment, and the histology need not be so thoroughly known in forming plans of treatment. On the whole, I prefer the expectant plan of treatment, which does not incur immediate danger from the operation.

Dr. E. E. Montgomery agrees with the author, that adenoma of the mammary does become carcinomatous, and coincides with the view that extirpation of the mammary gland, in its entirety, should be effected. That the occurrence of a single instance like the case narrated this evening should be possible, is sufficient to determine the employment of radical measures in order to avoid similar catastrophes. Many ladies, when cognizant of a tumor, become morbid and live in constant dread of cancer. Their lives are thus blighted and their usefulness impaired.

The psychical influence must not be overlooked, and should be a factor of considerable attention. The relief of mind following removal of a tumor, and the happiness ensured, should be of sufficient import to alone demand operation.

In closing the discussion, Dr. Beates remarked that it was this spirit of conservatism recommended by Dr. Hall that he especially desired to meet. He does not believe it proper to delay and postpone the only chance of cure until carcinomatous changes have occurred and the patient is constitutionally involved and rendered incurable. The danger of the operation is nothing in comparison to the great and fatal consequences of cancer, and should not be given a thought. The complete understanding of the histology is an essential, and its absence may easily explain the apparent rarity of adenoma. Surely adenoma is not a neoplasm of recent years; it certainly affected the mammary gland as long as woman has existed. That it has not been recognized, and when seen, been associated with various degenerations, or again when marked by preponderating pathological elements and not perceived is attributable to the fact that the histology and morphology has been neglected and not understood. In his limited experience, no less than five instances of œdema, verified by microscopical study, have been met with. He believes that

many tumors of doubtful nature were primarily pure adenoma, which, if they had been removed, would have resulted in complete cure and salvation from malignancy. The proneness to epithelioma or carcinomatous degeneration of the cervix uteri, after the menopause, is a fact widely known. The intimate sympathy existing between the mammary gland and the reproductive system, of which, indeed, it may be considered a part, affords additional cause to infer that such catastrophe might rationally be expected in the neoplasm under consideration, especially as it is already the product of morbid processes. Had this plan of treatment been adopted early in the history of Case No. 3, she would not now be a victim of cancer. With these views he recommends the treatment above set forth.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Annual meeting, held at Dr. Chas. Turnbull's, 1702 Chestnut street, on Friday evening, May 26th, 1882.

Dr. J. Solis Cohen in the chair.

Dr. Brose, by invitation, exhibited a case of Ludwig's angina, of which he gave the following history:—

B. R., aged twenty-one years, single, habits temperate, no history of syphilis. Father died at the age of fifty-three years; cause unknown. Mother living, and in good health. Has brothers and sisters, and as far as he knows they are in perfect health. Three weeks ago he caught cold, and then complained of cough, difficulty in swallowing, but had no enlargement of the neck until a week later, when he noticed a swelling on the right side. This was soft, and was seated below the inferior maxilla, extending from the anterior margin of the sterno-mastoid muscle to the median line of the neck, embracing the thyroid gland. There was no tenderness on pressure nor difficulty in breathing. He consulted a physician, who advised a flaxseed poultice, which being applied, the swelling and accompanying symptoms disappeared. The swelling remained away two days, when the door and windows of his room being left open at night, he again caught cold. The right side of the neck now became swollen and very hard. He was unable to swallow solids, and complained of dyspnœa. The swelling gradually became smaller but harder, until his admission into the wards of Dr. F. H. Gross, at the German Hospital, May 16th, 1882, when he presented the following symptoms: breathing unobstructed, swallows liquids with some difficulty, but is wholly unable to take solid food. The enlargement on the right side of the neck, a very hard and firm mass, extends from the inferior maxillary, embracing the submaxillary gland, downward, three inches; from the sterno-mastoid muscle behind to the median line of the neck in front, embracing the thyroid gland. There was no pain on pressure, and the local temperature was but little above that of the opposite side. His axillary temperature ranged between 98° and 100° F., being always from ½ to 1° higher in the morning than in the evening. On passing a bougie, an obstruction was encountered at the beginning of the œsophagus.

The treatment has consisted in mercurial inunctions, and the tumor has diminished much in size but retains its hardness.

At present the patient swallows solids without difficulty, and the remains of the swelling consist of a hard mass, situated in front of the sterno-mastoid muscle, at the level of the upper border of the larynx. The patient was discharged cured, June 12th.

Remarks were made upon the case by a number of the members, Dr. Cohen observing that the description seems more as though it was a diffuse inflammation of the connective tissue of the neck, or Ludwig's angina, as in disease of the thyroid body, acute thyroiditis, the tumor would extend below the level of the larynx.

Dr. J. Solis Cohen read a paper on "Rigidities of the Crico-arytenoid Articulation."

The following officers were elected for the ensuing year: President, Prof. Harrison Allen. Secretary, Dr. Geo. Y. McCracken. Executive Committee, Drs. J. Solis Cohen, Chas. Turnbull and Chas. E. Sajous.

On motion, a vote of thanks was tendered to the retiring President.

EDITORIAL DEPARTMENT.

PERISCOPE.

Chronic Cerebral Meningitis.

In the *British Medical Journal*, Dr. A. Hughes Bennett reports the following interesting case: The subject was aged 37, of no occupation. The father of the patient, who was otherwise a healthy man, was said to have had several attacks of temporary paralysis affecting the right leg and both arms. These seizures came on suddenly, and their effects lasted from a few days to several months. Otherwise, the family history was healthy. The patient himself appeared to have enjoyed perfectly robust general health all his life till the present illness. He was born in Australia, and remained there till a few years ago, engaged in active and healthy pursuits. Since his residence in England, he had passed his time in country and outdoor occupations, and had always been noted for his activity and strength, as well as for his intellectual acumen. At the age of fifteen, on awaking one morning, the patient discovered weakness in one of his arms; this soon passed away. Since then he had been liable to attacks of a similar nature. Being in his usual good health at night, next morning he would find one or more of his limbs on the left side weak. This paresis lasted from a few days to some weeks, and on one occasion as long as six

months. The paralysis was not complete; and, when it affected the leg, did not prevent the patient from walking, but only caused him to be lame, and drag the toes along the ground. When the arm was attacked, it was weak; and there was numbness, especially on the ulnar side. In the intervals between these seizures he was perfectly well, and there was no trace of impaired motion. Even when the paresis was present, he could, as a rule, take a great amount of exercise; but on several occasions, when it was severe, he was completely laid up. He had never had syphilis, or any other cerebral symptoms, and was not aware of having had "fits" or attacks of any kind.

About the middle of September, 1880, the patient, being in his usual good health, was seized with a severe pain in the epigastric region, and with an illness which laid him up in bed for six weeks. It appeared to be confined to a spot about the ensiform cartilage, was increased on pressure and after food, and was modified by position. There was a little vomiting; but no blood was ever seen in the ejected matter. The medical men in attendance believed the affection to be ulcer of the stomach. At the end of six weeks the symptoms passed away; the patient became convalescent; traveled to London; and for the next three weeks, although generally weak, considered he was rapidly improving in every way.

On November 21st the patient was seized with a severe pain in the epigastrium, which again compelled him to apply for medical assistance.

Present Condition.—The patient was very tall, (said to be 6 feet 5 inches in height), of spare yet robust build, pale and somewhat thin, from his recent illness. He complained of a severe, dull, aching pain at the ensiform cartilage. This was not influenced by pressure, but was increased after food, although not to a great extent. There was nothing to be seen or felt locally. There was no vomiting, nor other symptoms. All the organs were healthy; but the patient was slightly feverish, greatly depressed in spirits, and had a look of much anxiety and suffering. This condition continued without change during the next five days, the pain occurring in paroxysms of an extremely severe character, leaving during the intervals a dull, aching sensation. On November 25th the urine was found to be loaded with bile; and on the following day the patient presented all the usual appearances of jaundice. For the following three weeks the condition remained much the same; and there was almost constant pain in the epigastrium, increased frequently by paroxysms of a very acute character. There were also griping pains in the abdomen, especially before and after a stool. The bowels were constipated, and there was well-marked jaundice; no vomiting or headache; no œdema or anasarca; and the appetite was fairly good. The most careful and repeated physical examinations failed to detect anything abnormal. About December 19th all the symptoms gradually began to diminish in severity; abundant bile appeared in the stools; the urine became clear; the yellow color of the skin perceptibly faded; and the epigastric pain was much relieved. The general improvement so advanced, that in a few days the patient became quite convalescent, was able to sit up, and, with the exception of great weakness and emaciation, felt in good health and spirits. This continued until January 1st, when he was suddenly seized with an acute, lancinating pain in his head, accompanied with feverishness and great depression, which lasted during the day, and which was finally relieved by a hypodermic injection of morphia. A few days subsequent to this, a return of his former complaint was observed; namely, paresis of the left leg. The extensors of the foot were paralyzed; and, when the patient walked, he was very lame, and the toes dragged along the ground. The extensors of the thigh were also weak. All the flexor muscles seemed to be normal. The extension of the left hand was somewhat impaired, but otherwise the limb was unaffected. There was no loss of sensibility. With this exception, the general convalescence progressed favorably till January 6th, when the patient stated that he had a "fit." He said he had a repetition of this seizure on the following day. During the succeeding twenty-four hours he had two more attacks, one of which was witnessed by Mr. W. L. Purves (who watched the case with me throughout), and who described it as a genuine epileptiform fit. There were sudden convulsions of all the limbs and face, and complete loss of consciousness, lasting for some minutes. Immediately afterwards the patient was weak and depressed, otherwise well. Next day there was distinct paresis of the right arm, and the face was drawn slightly to the left; no other cerebral symptoms. The paresis of the arm gradually increased till January 12th, when its movements were very feeble and imperfect, and the grasp of the hand was almost lost. The patient then was depressed and emotional, but his intelligence was perfect. There were now slight thickness of speech and hesitation in articulating. On the following day the right arm was absolutely paralyzed as to motion, but the sensibility was unaffected. Two days later the right leg was found weak; there was considerable difficulty in articulation, and the patient spoke in a mumbling way. The movements of the tongue were sluggish; and, when protruded, it was pushed toward the left side. The face was distinctly drawn toward the left. In addition to the difficulty of articulation, there was evidence of partial true aphasia, as the patient had difficulty in selecting and recollecting suitable words with which to express himself; but he never employed wrong ones. His understanding seemed intact. Till January 17th, all these symptoms rapidly increased, when, in addition, he was attacked with severe pain in the back, with cramps and contractions of the legs. The patient was dull and apathetic, but appeared to understand what went on around him. His speech was now unintelligible. All the symptoms increased, and on January 22d the whole of the right side was completely paralyzed. Although the patient could not say a word, he appeared intelligent, and understood what was said to him. On the 28th the patient was evidently becoming weaker, the sphincters began to be relaxed, and the catheter had to be used.

From this date to February 8th he gradually sank, became comatose, and died.

A post-mortem examination was made, from which it was concluded that the patient, in early life, without apparent cause, was afflicted with chronic cerebral meningitis, which, for many years, caused no symptoms except occasional attacks of temporary hemiplegia. The changes in the tissues and circulation thus induced may have afterwards been the starting-point of the chronic abscess, which existed for a long time, without producing any symptoms. Five months before death the patient was seized with an acute attack of limited peritonitis, involving the portal system, and subsequently causing thrombosis and obstruction of these veins. The constitutional disturbances induced by the second attack of this illness probably excited the recent acute action in the brain, in the shape of cerebro-spinal meningitis, and the extension of the already existing abscess.

Successful Gastrostomy.

In the *Lancet*, Mr. Thomas Bryant records a successful case of gastrostomy, for cancer of the œsophagus. The patient, a male, aged sixty-five, had enjoyed good health up to the winter of 1879 80, when he occasionally suffered from fainting fits, and was greatly troubled with dyspepsia. He grew gradually worse, and finally exploration revealed a stricture at the lower end of the œsophagus. Gastrostomy was determined upon, and the following operation was performed on Dec. 3d, 1881: The bichloride of methylene was used as an anæsthetic, and the carbolic spray was employed. An incision three inches long was made about half an inch below the margin of the left ribs and parallel with them; the skin and muscles were consecutively divided down to the peritoneum; all bleeding vessels were twisted as they were divided, and all capillary oozing was arrested by a wet sponge. The peritoneum was then divided, and the stomach, which presented itself, was at once seized, care being taken at this time to keep the wound well sponged, to prevent anything passing into the peritoneal cavity. The stomach was brought well forward through the wound, by means of two loops of fine carbolized silk, which were inserted through the peritoneal covering of the stomach, about one-third of an inch apart. The ends of these loops were left long, for a purpose to be described later on. The stomach was next carefully fastened, by a series of interrupted silk sutures, to the margins of the wound, the sutures including the parietal peritoneum with the muscles on the one hand and the peritoneal coat of the stomach on the other. The stomach at this stage of the operation was not opened. The wound was dressed with a mixture of one part of terebene and three of olive oil, a half grain morphia suppository was given, and small nutrient enemata of four ounces of milk and beef tea, with ten drops of laudanum, were ordered to be given every four hours. The patient progressed well, and on the eighth day after the primary operation the stomach was opened by making a puncture through its coats with a tenotomy knife, one-eighth of an inch wide, having gently elevated the exposed surface of the viscus by means of the loops of silk left long for this purpose. All the sutures were removed. A tube the size of a No. 9 catheter was then introduced through the artificial opening into the stomach, and the patient fed with a few ounces of warm milk, none of which escaped on the removal of the tube. He was now fed partly by enema and partly by the introduction of food into the stomach through the artificial opening, the use of the latter being gradually increased day by day. The stomach bore the food well. The routine of feeding by the stomach, three weeks after the last operation, is reported as follows: 9 A. M., milk, one egg and two drachms of brandy; 3 P. M., beef tea, with finely minced pancreas; 9 P. M., milk, egg and brandy; 3 A. M., milk, egg and brandy. On the thirty-sixth day it is noted that he is gaining strength and is able to sit up daily.

January 25th. Mr. H. is now able to come down stairs, but the effort of walking up again causes great fatigue and slight swelling of the legs. The wound is nearly healed and looks dry. The orifice of the artificial opening into the stomach appears as a dimple. There is no difficulty in introducing the tube for feeding purposes. He takes four meals daily very well. Bowels act well. Urine healthy. Bad temper is his only drawback.

March 20th. Three months and a half after the operation, Mr. Stephens reports: "After the operation Mr. H. steadily gained weight until about Feb. 18th, since which time he has been, I fear, going down hill. There is now scarcely a trace of the wound, only the artificial orifice. He is fed regularly every six hours by the tube in his stomach, but takes some new milk daily by the mouth, and milk with coffee or tea occasionally. He is now steadily, but none the less surely, losing ground, and is unable to take as much food as formerly by the stomach."

To-day (April 2d) he reports: "Mr. H. is still getting weaker, though very gradually. Finds more difficulty in taking liquid by the mouth, and experiences pain in the right shoulder-joint at each gulp. The stomach retains food well. Bowels more regular, and motions healthier than they have been for many months. The nutrient suppositories are still of immense value. He remains down stairs daily for eight or nine hours, and gets about in a Bath chair." May 2d: At the present time he is as last reported.

In conclusion, Mr. Bryant says: "Let me summarize what I wrote a year ago when relating a case of gastrostomy for cicatricial stricture, at a sister Society (*vide The Lancet*, April 9th, 1881). That gastrostomy for cancerous stricture of the œsophagus should be undertaken as soon as there is a practical difficulty experienced in the deglutition of solid food, life being prolonged by such a practice, since the progress of the cancerous disease is retarded and much misery is saved. That the operation should always be divided into two steps, as suggested by Mr. Howse, and that the second step should be performed on the fifth, sixth or seventh day after the first, according to the repair in the seat of operation and urgency of the case. That the opening into the

stomach should not be larger than that made by an ordinary tenotomy knife, or about one-eighth of an inch, since such an opening is elastic enough, on the one hand, to admit a tube for feeding purposes, through which thick food can be injected with the feeding apparatus I employ, and on the other to close after the removal of the feeding tube, so as to prevent regurgitation of the stomach's contents, with its attendant evils."

Hypodermic Use of Amyl Nitrite.

Dr. J. J. Frederic Barnes thus writes, in the *British Medical Journal*:—

I have administered amyl nitrite hypodermically thirty or more times during the past eighteen months. In all cases a ten per cent. solution in rectified spirit was used. In no case did any untoward inflammatory or suppurative symptoms occur afterward. The action of the drug was immediate in every case, the subjective phenomena being like those experienced when using the ordinary methods of administration. The spirit solution appears to be an excellent preparation for use, as a small quantity kept in an ordinary stoppered bottle for some months retains its full efficiency at the present time. The dose usually administered has been ten minims of the solution, equal to one minim of amyl nitrite. In lumbago, where the patient is seen at the commencement of the attack, and the disease is not of long standing, the drug given in this manner instantly relieves the symptoms; a patient who is unable, previously to its administration, to bend the trunk without the most exquisite pain, five minutes afterwards can do so quite readily. In a case of paraffin poisoning, where the patient was in a state of collapse and almost pulseless, one administration (inhalation having been ineffectually tried) brought on an immediate resumption of cardiac function, the man speedily recovering. Its action in this case would, I apprehend, be due to the relief momentarily given to the congested centres by the peripheral hyperæmia induced. In another case, one of duodenal colic, the patient was found rolling on the floor, from the acuteness of the pain; when, on injecting fifteen minims of the spirit solution, the pain disappeared as if by magic, and the patient was at once able to resume his ordinary position. The value of this drug by ordinary methods of administration has already abundantly demonstrated how great a boon the discovery of Dr. Lauder Brunton is in the hands of the profession, notably in cardiac angina; and I feel confident that its utility may be still further enhanced by giving it, as here recommended, hypodermically.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Another edition of "The Vest Pocket Anatomist," by Dr. C. Henri Leonard, indicates that the popularity of this little manual is unabated. It is published by the author, Detroit, Mich.; price 75 cents.

——Dr. John C. Morgan, a respected homœopathic physician of this city, has written a little work on the "Diet of Infants and Young Children." It is a ground on which all "schools" can meet. His opinions are generally sound, except that he gives too indiscriminate praise to the various "prepared foods," and in some of his recommendations, as giving new cider to young children, he is too liberal. (James Hogan, Phila; price 25 cents).

——Dr. Radcliffe, of Washington, in a paper on the treatment of uterine fibroids with iodine, gives an ample bibliography, and states his own results as follows: "I have learned this much from treating quite a number of cases—cases probably in the incipient stage, and due probably to simple hyperplasia or proliferation of tissue—that by iodine the hemorrhagic status is changed, the menstrual periods prolonged or made regular, their approach and attack shortened, and the interval made more comfortable."

——"Iodoform gegen Diabetes Mellitus," is the title of an important contribution to therapeutics, by Prof. J. Moleschott, of Rome. He details five cases in which iodoform very positively benefited in this serious disease To prevent the unpleasant eructations he combined it with cumarin. His usual formula was—

℞.	Iodoformi,	1.0
	Ext. lactuc. sat.,	1.0
	Cumarini,	0.1.

For twenty pills; powder with gum arabic and take from one pill twice daily to two pills four times daily, gradually increasing. Cumarin, it will be remembered, is the odoriferous principle of the tonka bean.

——The Alumni Association of the Albany Medical College has published the Proceedings of their Ninth Annual Meeting. President Vanderveer delivered the address, and made an earnest plea for the *moral* improvement of the profession. He most justly says:—

"Medical colleges cannot do all that is needed at the present time to improve the condition and standing of what we so love to mention as one of the three learned professions. They are making some effort in various directions, but the facilities and inducements in some portions of the country to organize new schools are such as to cripple seriously the good that is being done. I am sure that all the quackery exercised in the present day does not do as much harm to the practice of medicine as do the self-advertising, immoral and unworthy men in our ranks."

A number of prizes are offered for competition, to the alumni of the college.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SURGICAL PROVISIONS ON RAILROADS.

We had just sent to press the remarks we lately made on the propriety of railroad companies providing the most immediate necessities in case of accidents, when we received a printed circular from the Denver and Rio Grande railway company, describing its "Train Medicine Chest."

This chest, with the printed instructions, is supplied to every passenger train. Its contents are as follows: Laudanum, ammonia mixture, styptic collodion, bicarbonate of soda, styptic cotton, surgical needles, silk, wax, sponges, adhesive plaster, bandages, lint, scissors.

The printed circular contains directions for the use of these in case of accidents, and also for the immediate treatment of emergencies such as are likely to occur. These include bleeding wounds, fractures, dislocations, burns and scalds, frostbite, rupture, fainting, shock, etc. The advice is presented in plain terms, with the utmost brevity consistent with clearness.

This line has also organized a regular staff of surgeons whose duty it is to respond at once to every call upon them from the employees of the road. The circular says:—

"Whenever an accident occurs on the line, the conductor must immediately telegraph the surgeon in whose charge the injured person is to be placed, in order that time may be given to prepare for reception of the patient.

"In case of injury inflicted by trains upon intoxicated persons on the track, tramps stealing a ride, etc., where the employees of the road are in no way to blame, the injured person must, of course, be carried to a station where humane and proper treatment can be bestowed; but, as such persons are generally without means, it is not advisable to take them out of the county in which the accident occurs, for, if removed beyond the county limits, the company may be held responsible for treatment and support."

We believe the preparation and distribution of this circular, and the organization of the staff, are due to the skill and energy of F. J. Bancroft, senior surgeon of the road, who deserves much credit for the measure.

It is one which ought to be extensively adopted throughout our country. The traveling public should be protected in regard to their health and safety in every possible way. This is little enough to ask of these corporations, which in turn are always asking so much of the public.

PRESCRIBING BY DRUGGISTS.

This much mooted question is still an open and undetermined one. But recently a death occurred in England from a supposed blundering prescription of a druggist, which gives fresh interest to the subject, and causes us to think a few words not out of place. In this case the coroner held that the responsibility of the druggist did not cease when he had wisely prescribed a drug that would not kill, but that the question then arose whether one more competent, whether a skillful physician, might not have ordered such medicine as would have effected a cure. There are two sides to every question, and it is but just that they should both be stated. It is a very prevalent notion among the public, not confined to the ignorant, but participated in, to a great extent, by the intelligent classes, that a druggist has a medical education. It is a very common thing

to hear him addressed as Doctor. Because he deals in and dispenses drugs, the public, without stopping to consider, hastily conclude that he is acquainted with all their properties and uses, and to a certain extent this idea is correct. But they fail to realize, because they have never been told, that the successful practitioner of medicine must know more than this. The art of diagnosis they know not of, neither does the druggist, and here comes in the fatal danger of "prescribing by druggists." One could hardly expect the ordinary druggist, when a man enters his store and asks for something for a sick stomach, or a sick headache, or a toothache, earache or constipation, to refuse to prescribe, since he would lose a sale of his wares by so doing. And in these trivial cases, likely enough, any intelligent druggist is fully capable of prescribing correctly. But where will the dividing line be drawn. We all know that some of the most serious and fatal diseases at times present but insignificant outward or ordinarily appreciable symptoms. In this fact we find the argument against "prescribing by druggists." We must ever bear in mind the fact noticed by the English coroner, that through ignorance of the true nature of the malady afflicting the individual, death may be allowed to ensue, on account of the inappropriateness of the remedy prescribed. Even conscientious druggists fail to realize this aspect of the question. Again, there is another danger. We are all human and are all liable to err. Supposing a man enters a drug store, and complaining of diarrhœa, asks for a remedy. It may happen that the druggist is very busy, or his mind may be pre-occupied in some other way, and he may therefore thought lessly prepare a mixture containing fatal doses of opium. Doctors are liable to make the same error, it is true, but the prescription passing through the hands of the druggist, the overdose is likely to be detected ; it is hardly possible that *two* men will allow the error to pass unnoticed. Still, again, it is impossible to say that *intelligent* and *capable* druggists may prescribe in trivial cases, for who is to decide of the capability and intelligence of the man. This freedom of prescribing by druggists, which is, at least tacitly, recognized in our country, opens the door to untold evils. The majority of druggists are men of very little education outside of their regular business, and when they undertake so important a duty as prescribing for the sick, they are all the time in danger of some fatal error. It has been said that "*any fool can find fault, but that it takes a wise man to find a remedy.*" We confess that it is somewhat difficult to find a remedy for this evil. We can see such only in legislation. In theory it is believed and universally admitted that it is the duty of the physician to ascertain the nature of the malady from which his patient is suffering, and to prescribe the remedy, and that it is the duty of the druggist to compound such prescription. This is the theory, and it is plain enough; if carried out in practice all would be well. If now it were made a punishable offence for any druggist to prescribe, the end desired might be accomplished.

FREE DISPENSARIES AND YOUNG PHYSICIANS.

Charity covereth a multitude of sins, we are told, and it is truly a virtue that deserves great encouragement. But we can go too far in any good work, and it has now become a question for the attentive consideration of philanthropists, whether we have not in our large centres of population ample accommodation for the charitable and gratuitous medical treatment of our indigent citizens. It is a fact, and it is a shame, that many well-to-do persons, for one reason or another, and usually because of a miserly disposition, will resort to hospitals and dispensaries for free treatment, when they are amply able to liberally reward a physician for his services. We know of one case, where a woman afflicted with an ovarian tumor desired to be operated upon by a certain surgeon. He advised her to take a room in the hospital with the surgical staff of which he was connected. This lady's husband was sufficiently wealthy to enable him, before the operation, to give $15,000 in charity, and to pay some twenty or twenty-five

dollars a week board for his wife. The operation was performed, and the surgeon was compelled, in person, to dress the wound twice daily. He sent in a bill for five hundred dollars, which was refused him, on the technical ground that because he was a member of the staff (from which he received no remuneration), he had no right to charge any inmate of the house, even though, as in this case, the person in question was a *private* patient, sent to the hospital for good nursing. The authorities of the hospital supported the patient, and dismissed the surgeon from the staff. We are glad, however, to say that the courts of law took a more just view of the case, and gave the Doctor a verdict for his bill. It is only natural for persons to prefer going to a first-class hospital where they can receive *for nothing* the opinion and advice of the very leaders of the profession, rather than to seek some young, well informed, but obscure physician, and *pay* him for his services. In some places the old and great men of the profession are very high priced. None but the very wealthy can afford to enjoy their services for more than a mere consultation; while in other localities we find the leaders doing professional work as cheaply as the most recent graduate.

It is these two points that make the pathway of the young physician so hard and rugged. We would say to any young doctor casting about him where to locate, look for a place where free hospitals and dispensaries are very scarce; then inquire about the prices charged by the leaders; if they are very high you can settle down with a fair prospect of success, providing you take with you the two personal elements necessary to success in our profession, viz.: a good moral character and a thorough medical education.

Notes and Comments.

Strangulated Inguinal Hernia.

In the *Med. Press*, Mr. Norton relates the following case of a man, an old soldier, aged 59, who had had an inguinal hernia on the right side for thirty years. The rupture had given him much trouble at times, but the patient had always succeeded in reducing it himself.

On the 21st of December, 1881, the rupture came down while the patient was laughing, and he found himself unable to return it, after using a good deal of force.

On admission to the hospital the patient had much pain about the abdomen and was vomiting stercoraceous matter. The tumor was about the size of an orange and very tense. The man was put under ether, and the rupture not yielding to gentle taxis, an operation was performed in the usual manner. On the sac being opened, the cyst was found of a dark purple color, with abrasion of the peritoneal surface. After the constriction had been divided and the gut was being gently returned, it suddenly burst at the seat of abrasion, the contents of the intestine flowing over the wound. After the constriction had been more freely divided, the edges of the gut were stitched to the skin by silver wire. The patient vomited much during the operation, and immediately afterwards. On being put to bed a poultice was applied over the wound, and one-quarter grain opium given every hour, with teaspoonfuls of brandy and milk and soda water.

On the 22d patient was very prostrated, having vomited severely during the night, and complained of a good deal of abdominal pain. Pulse at 11 A. M. 135, and very weak.

On the 23d the vomiting continued at intervals, but not so severely, pulse being 120, stronger, and the abdominal pain much less, very little fecal matter at present coming from the wound.

On the 24th the vomiting still continued somewhat, but the abdominal tenderness had gone, and patient was able to take iced milk, and soda water and beef jelly fairly well.

On the 30th the man was quite free from all symptoms of vomiting, the wound was looking healthy, and a large quantity of liquid matter coming away.

On the 2d January, 1882, a soft pad, kept in place by an india-rubber bandage, was applied over the wound to prevent the discharge from constantly trickling over him and causing skin irritation. At this time the patient was eating and sleeping well.

On the 19th January, the intestinal flow having stopped for twelve hours, the patient was seized with severe vomiting, and brought up about a pint of stercoraceous matter; an india rubber tube was then with difficulty inserted, and a large quantity of liquid matter drawn off; this gave him instant relief. From this time a tube was passed twice daily and left in two or three hours, its passage being attended with some diffi-

culty, owing to the gut shifting its position. The patient went on in this way till the 18th of February, now and then sitting up in a chair with his pad on.

On February 19th vomiting began again severely, nothing flowing through the tube for some hours. After the bowel had been well relieved by the tube, the vomiting still continued incessantly, and the patient died of exhaustion on the 21st of February, two months after the operation.

Post-mortem.—On removing intestines the obstruction was found about a yard and a half from the ileo-cæcal valve; above this the gut, when distended with water, was two inches in diameter; below the stricture the diameter was about half an inch. About six inches above the valve was another doubling of intestine, which was fixed by adhesions. Water passed freely through this part, although the bowel was dilated above it. The duodenum and jejunum were otherwise normal. The cæcum contained several hard scybala.

Differential Staining of Nucleated Blood Corpuscles.

In the *Microscope*, Dr. Allen Y. Moore says that it has been urged against the differential staining of histological structures, that the process may induce an alteration which may be mistaken for the normal condition. That this is, in many cases, true, is beyond question, but the exceptions are far too numerous to justify it as a rule.

For some years past he has used a process for the double staining of nucleated blood corpuscles, which causes no alteration, except of course in color, and as the structure can be seen much better in a semi-transparent than in a more perfectly transparent body, the corpuscles thus stained offer advantages for study which are not found in those left unstained.

The fluids used for this purpose are two, which he designates as A and B. Their formulas are as follows:—

A.

℞.	Eosin	gr. v
	Distilled water,	ʒ iv
	Alcohol,	ʒ iv.

Sig.—Dissolve the eosin in the water and add the alcohol.

B.

℞.	Methyl analin green,	gr. v
	Distilled water,	ʒ j.

The blood should be spread upon the slide, by placing a drop upon one end and quickly drawing the smooth edge of another slide over it. This, if well done, will leave a single layer of corpuscles evenly spread over the central part of the slide.

When the corpuscles on the slide are thoroughly dry, which will only require a few minutes, the slide should be "flooded" with stain A.

This should be allowed to remain on for about three minutes, at the end of which time it may be washed by gently waving back and forth in a glass of clean water. Before it is allowed to dry, the corpuscles should be again flooded, this time with stain B. After two minutes' exposure to this fluid the slide should be washed, as before, and set away to dry. When dry, a drop of Canada balsam may be put upon the blood, a cover-glass applied, and the whole gently warmed until the balsam spreads out properly. When hard, it may be finished the same as is usual with balsam mounts.

If now examined with the microscope, the corpuscles will be found to be well stained with red, while the nuclei and "leucocytes" will be a blueish-green.

The granular appearance which is ordinarily seen in the nuclei now shows with a vigor and sharpness which is difficult of description, while the whole corpuscle is as brilliant as a newly-cut ruby.

Boracic Acid for Granular Lids.

Dr. James L. Minor says (*Va. Med. Monthly*) that he has found boracic acid powder a most excellent application to granular lids. It is used as follows: The lids being thoroughly everted, the powder is spread freely over the whole conjunctival surface with a camel's hair brush. The acid is generously applied, and mixing with the discharge from the lids, it readily gains access to the cracks and crevices between the granulations, and thus comes into direct contact with the entire surface upon which it is intended to act. The immediate effect is to increase lachrymation and to cause a burning, gritty, sensation, with some pain. These symptoms usually pass off within ten minutes, and are followed by an amelioration of all the symptoms which existed before the application of the acid. The granulations may look less gorged and prominent, but he has not been able to discover much change in the naked eye appearance of the conjunctiva after one application. The powder was used three times a week. The improvement is so gradual that it is almost imperceptible as it progresses, but Dr. Minor has derived more satisfactory results from the use of this powder than from the ordinary caustic or astringent applications.

Fracture of Thyroid Cartilage

Mr. Reginald Harrison reports the following case in the *Lancet*:—

J. W. B——, aged sixty-three, a dock laborer, was admitted on March 28th, 1882. A few hours previously he had been kicked on the throat, upon which swelling and difficulty in breathing rapidly supervened. On examination, there was considerable swelling over the front and sides of the larynx. As the difficulty in breathing was rapidly increasing, Mr. Harrison advised that tracheotomy should be performed without delay, it being probable that the symptoms were due to a fracture of the thyroid. Mr. Harrison's house-surgeon, Mr. Rayner, accordingly, at once opened the trachea and put in a tube, at the same time verifying the diagnosis that had been arrived at. The patient, after the operation, was kept in an atmosphere well charged with steam, and for four days was fed by the rectum, after which he was able to take liquid food by the mouth. The tube was removed on April 8th. The wound rapidly closed, and the patient left the Infirmary on April 25th, some slight huskiness in the voice alone remaining. Mr. Harrison commented upon the extreme rarity of such injuries. Tracheotomy had undoubtedly saved the patient's life. The age of the patient had probably induced changes in the cartilage, which had somewhat added to its liability to fracture on the application to it of force, such as a kick.

Uræmic Convulsions and Coma Treated with Chloroform and Salicylate of Soda.

Dr. Thomas A. J. Cocksedge reports the following case in the *Lancet*:—

On the 28th of April I received an urgent message to attend the Rev. C. M. He had been under my charge for some weeks, as he was suffering from chronic desquamative nephritis, complicated with asthma. His kidney disease is, I believe, of nine years' standing. I found him semi-comatose, and during the day he gradually lapsed into a condition of profound coma. Convulsions came on about 1 P.M.; they occurred at first at intervals of about one hour, and as the day wore on, although less violent, with intervals of about twenty minutes. His last convulsion took place about midnight. He was seen by Mr. Martin Coates, of Salisbury, with me, about 11 P.M. He was then perfectly comatose, the pupils being quite insensitive to light. Mr. Coates considered him to be in a desperate condition, and I confess that I quite agreed with the prognosis. However, on visiting him again, after Mr. Coates left, I found the convulsions so much less violent that I became more hopeful. The next day there had been no recurrence of the spasms, and he steadily progressed toward recovery. The treatment of the case was as follows: Mustard and water were applied to the feet. Turpentine enemata were injected into the rectum. Podophyllin and jalapine were given by the mouth, being introduced through a quill. The surface of the body was sponged over with vinegar and water, and profuse diaphoresis was thus induced. Chloroform was administered by inhalation, during two of the severest spasms. On the second occasion, however, I noticed that respiration was with such difficulty reëstablished, that I did not venture on a third administration of this remedy. Before leaving, on the morning of the 29th, I gave him an enema, almost as hot as I could bear my finger in, of very weak mutton broth, this being the first food which he had taken since his evening meal of the 27th. On the 29th, as soon as he was able to swallow, I gave him seven and a half grain doses of salicylate of soda, in weak milk and water, every six hours.

Painful Affection of the Wrist.

In the July number of the New York *Medical Journal and Obstetrical Review*, Dr. Edward H. Bradford, Surgeon to Out Patients, Boston City Hospital, relates three cases of a painful affection of the wrist, the features of which were: pain referred to or most severe at the middle of the carpus; slight swelling; an absence of constitutional disturbance, and with no interference, or but partial interference, with motion of the articulation between the carpus and the radius and ulna. The symptoms were relieved by fixation, and recovery took place, finally, after a period of rest. The author considers them examples of synovitis of the carpus.

The Ergotine Treatment of Uterine Tumors.

In the July number of the New York *Medical Journal and Obstetrical Review*, Dr. Wm. T. Lusk, Professor of Obstetrics in Bellevue Hospital Medical College, relates a case of fibromyoma of the uterus, in which ergotine injections into the subcutaneous tissue of the abdominal wall over the tumor, not into the tumor, resulted in a rapid diminution in the bulk of the growth, at the expense, however, of gangrene of the compressed tumor, ending in fatal septicæmia. While some few cases of recovery by use of these injections are on record, they cannot be said to have gained the confidence of gynecologists.

Morphia Hypodermically as an Adjuvant to Chloroform.

Dr. Andrew S. Currie, in the *Lancet*, calls attention to a paper on this subject in the *Practitioner*, by Dr. Alexander Crombie, which he considers has not received enough attention. Dr. Crombie states that in 600 cases, in only one was there any evidence of asphyxia, and in that instance the usual precautions had been neglected. The method employed is very simple, and consists in the hypodermic injection of morphia immediately after beginning the administration of chloroform. I have recently employed a modification of this plan with the greatest comfort to the patient and to myself. About ten minutes before administering the chloroform I inject a full dose of the liq. morphiæ hypod. (B. P.). The chloroform is freely sprinkled on a piece of lint folded twice, and one dose is, as a rule, sufficient to induce complete anæsthesia.

Dr. Currie says that having, a day or two ago, to open a large abscess of the thigh, in the case of a lady who has been an invalid for the last ten or twelve months, I induced anæsthesia easily and rapidly in this way. The patient, who has repeatedly had chloroform administered for confinement, tooth extraction, etc., assured me that she had never before taken it with such a total absence of all feeling of discomfort. There was no sensation of suffocation and no trouble with after-sickness, which had on previous occasions proved troublesome.

Codeia in Diabetes.

In the *British Medical Journal*, Dr. R. Shingleton Smith relates some cases of diabetes treated by codeia, in which this drug produced very good effects. It has a remarkable power of checking the elimination of sugar, and a corresponding improvement in the health of the patient results. It would appear that alkalies and all other methods of treatment are far inferior to the treatment by codeia, which may be considered to have almost a specific action on the disease. The facts seem to justify decided language with regard to the use of codeia, which should not be permissive, but imperative, in all cases of advanced diabetes mellitus; whatever else may be given, codeia should first be given, and in fairly large doses, until some physiological effect is produced. Even dieting appears to sink into insignificance, alongside of codeia, and in one case this drug alone was sufficient without any dieting, the patient being on a mixed diet all the time. In all the cases reported there was marked improvement while taking the codeia, which ceased when it was withheld, and was renewed on its repetition. Morphia had a good effect in two cases, but the improvement with it was much less marked than with the other alkaloid.

Treatment of Scars of the Face.

A most important branch of cosmetic surgery is treated by Dr. C. L. Bull, of New York, in a reprint from the *Transactions* of the Ophthalmological Society. He says: "Persistent rubbing and kneading of scars of the face, both those due to burns and those resulting from bone caries, as preparatory to blepharoplasty, have, in a number of instances in the writer's experience, yielded most excellent results. Adhesions of scars, slight or extensive, to the subjacent parts, have been slowly, cautiously and painlessly detached, and a gradual absorption of the firm material in the dense part of the scar has been brought about. So considerable has been the result obtained in some cases that the writer has come to regard this gradual extension and loosening as an important part of the treatment in these cases." When one reflects on the amount of mental misery these scars often cause, their removal becomes an object of great importance.

Nitrate of Lead in Cancer of the Cervix Uteri.

M. Cheron, in the *Revue des Maladies des Femmes*, says that he has had very good results from the direct application of the nitrate, powdered, to the ulcerated cervix. After touching the ulcerated surface with glycerine, he injects about a quart of cold water, containing about a drachm and a half of tr. ferri perchlorid., and then dries the surface with absorbent cotton. Finally, the following powder is introduced, by means of a syringe made for injecting powders:—

℞. Plumbi nitrat., pulv., ℥ ss
Lycopod., pulv., ℥ j. M.

The powder is retained in place by a tampon of cotton. Through this means suppuration diminishes considerably, as also the bad odor. Even hemorrhage is not so profuse, and in some cases it is entirely suppressed.

Hydrobromic Acid.

Dr. W. B. Moir says, in the *Lancet*, that he has obtained some excellent results from the use of this acid. A young lady complaining of severe and frequent headaches, accompanied with flushing of the face, and at times with ringing in the ears, was encountered. She seemed

perfectly healthy, and there was no appreciable cause for this condition. She was ordered fifteen minims of the acid, thrice daily, after meals, in a little sweetened water. This treatment was continued for three weeks (the dose being increased first to twenty and subsequently to twenty-five minims). The happiest possible results ensued, and complete relief was afforded. Given in combination with quinine, he has found it to mitigate or entirely prevent the headache which often accompanies the use of that drug. In a case of persistent toothache, occurring during pregnancy, he obtained very satisfactory results from the use of this acid.

Special Reports.

NO. VII.—HEART DISEASES.

MALIGNANT ULCERATIVE ENDOCARDITIS.

In the *Medical Times and Gazette* Dr. Sidney Coupland records several cases of heart disease to which he prefixes the term *malignant* to denote simply the clinical fact of their fatal progressive course, without reference to their etiology. In two of the cases reported there was a previous history of rheumatism, while in a third there was no certainty but a probability of such history He calls particular attention to the irregular and pyæmic character of the pyrexia, which in one case was so strikingly periodic as to closely resemble intermittent fever. He believes that the combination of endocarditis with such a form of pyrexia is enough to justify the gravest prognosis, and to stamp the heart lesion as "*malignant.*" The cases recorded are all so similar in clinical history that the symptoms of one will serve to describe all. A man, forty-one years of age, had enjoyed good health all his life, with the single exception of an attack of gonorrhœa twenty years ago. Two months before admission to the hospital he took cold and was seized with pain in the left leg. The pain finally left him, but he seems not to have felt well, and five weeks before admission began to suffer from shivering fits. These attacks would come on at irregular intervals, sometimes every third day and sometimes every fifteen hours, so that he imagined he had the ague. Each attack was accompanied with vomiting, sometimes of food, sometimes of clear or bile-stained mucus, and was followed by an intense thirst and an intolerable sense of heat and discomfort. He was troubled with insomnia, lost his appetite and became very weak. He had no pain, but on December 31st, 1881, he noticed that his legs swelled a little toward night. He was admitted into the hospital January 3d, 1882, in the following condition: He was spare and sallow, face marked with acne rosacea. Much depressed and had a spell of shivering. Temperature 101.2°, hot and very thirsty. Not sweating. Tongue dry, glazed, cracked, but not coated. Physical signs of lungs practically normal. Cardiac dullness normal. Apex beat in fifth interspace one inch and a half below and half an inch to the sternal side. There is a rough systolic bruit at the apex; no thrill. The pulmonary second sound is ringing; the aortic is dull. Area of hepatic dullness normal, splenic increased, reaching from seventh to eleventh rib. Abdomen full and tympanitic. The temperature being the most marked and characteristic symptom, it was at first supposed that the man was suffering from ague, and quinine was administered freely, but had no effect whatsoever. The existence of the endocardial murmur and the great constitutional disturbance led to the diagnosis of malignant endocarditis of pyæmic type, which opinion was strengthened by the appearance of albumen, and later on of blood, in the urine. The following is the temperature record:—

January 4th. 2 30 A.M., 99°; 4 A.M., 102.8°; 8 A.M., 104°; 5 P.M., 99.8°; 5.20 P.M., 99.4°; 6.35 P.M., 103.6°; 10.15 P.M., 105.8°.

January 5th. 11.30 A.M., 100.2°; 12.20 P.M., 102.4°, 1.40 P.M., 104.2°; 4.45 P.M., 105.2°.

January 6th. 3.30 A.M., 98.6°; 5 A.M., 104°; 8 A.M, 105.2°; 9 P.M., 99°; 10.15 P.M., 103.6°.

January 7th. 2.15 A.M., 105°; 1 P.M., 97.8°; 2.30 P.M., 103.6°; 6.30 P.M., 105.2°.

January 8th. 5.30 A.M., 100°; 6.45 A.M., 103.6°; 10.45 A.M., 105.2°; 9.15 P.M., 98.40°; 9.30 P.M., 99.2°; 10.45 P.M., 103°.

January 9th. 2 A.M., 104.4°; 11.45 A.M., 99.2°; 1.30 P.M., 104.4°; 4 P.M., 104.4°.

January 10th. 1 A.M., 99.2°; 2.45 A.M., 100°; 4 A.M., 103.8°; 7 A.M., 103.8°; 3 P.M., 100°; 5.10 P.M., 103.4°.

January 11th. 5 A.M., 99.4°.

This is truly a curious temperature record, and one that would cause any physician to administer quinine, unless he bears in mind the present recorded cases. The pyrexial period, throughout the disease, averaged about five hours and a quarter. The patient grew gradually worse, the breathing became shallow and rapid, and death occurred rather suddenly on the afternoon of the 11th.

In one of the cases, shortly before death, the temperature fell to 95°. As a rule, ulcerative endocarditis is an acute disease, engrafted

upon already diseased valves, but exceptions to this rule are recorded. The natural tendency of endocarditis, from whatever cause, is to the formation of fibrinous deposits on the inflamed and altered tissue of the valves. These vegetations may and often do excite, by their friction against the walls of the heart or opposite valves, localized patches of inflammation proceeding to ulceration. In that way, cardiac aneurisms and aneurism of the aortic or mitral valve may be set up.

In the *Transactions of the Pathological Society* for 1876, page 73, Dr. Coupland recorded a case where a mitral aneurism originated from the friction of aortic vegetations. Several similar cases have been reported by Drs. Ogle, Moxon, Fagge, and Legg. Vegetating endocarditis may be *simple*, it may lead to embolism and to secondary ulceration, without presenting the clinical features of *malignant* or ulcerative endocarditis. Hence the term "ulcerative," as applied solely to these *malignant* forms, those in which the clinical history is rather that of septic fever than of heart disease, is misleading. For this reason, the term *malignant*, as originally employed by Virchow, has been used to distinguish these septic cases. There must be some element superadded to ordinary ulcerative endocarditis to impress upon it these peculiar clinical features of malignancy. That element has been discovered by Heiberg, and confirmed by Klebs, Osler, (*Seguin's Archives*, February, 1881, page 44), and others, in the presence of fungoid organisms in these vegetations. The clinical distinction has long been known, and the term *septic endocarditis* was in use long before the phrase *mycosis endocardii* came into being. Jaccoud, in the "Dictionnaire de Medecine et Chirurgie," Vol. xii, 1870, clearly discriminates between vegetating endocarditis and *septic* endocarditis. Quite lately Dr. Goodheart directed the attention of the Pathological Society to the fact that cases of vegetating endocarditis are prone to occur whenever septic disease is prevalent. In what manner the valves of the heart become the seat of this mycosis, it is impossible, with our present knowledge, to state positively, though many theories have been advanced. It must be remembered that the cardiac lesion may be the result and not the cause of the blood contamination. Once formed, however, the diseased vegetations become the foci for the metastatic dissemination of the septic organisms. Given, then, signs of endocarditis, with the above pyrexial type, and constitutional symptoms of a typhoid character, and there can be no doubt of the nature of the case, and of the lethal prognosis that must be made in the presence of such indications. Unfortunately, no mention is made of treatment, but in one case where uræmia seemed imminent, diuretics warded off the fatal termination for a time. It would seem, if the theory is true, of the parasitic nature of the disease, that antiseptics would, probably, have a good influence, though that question is yet undecided.

In the *British Medical Journal*, Dr. Samuel Wilks, writing about Ulcerative Endocarditis, says: "It is a disease full of interest and importance, for not only is its pathology obscure, but the symptoms are so often illy defined, that it is constantly mistaken for other complaints, and especially for the various forms of fever. The patient is generally in a highly pyretic state, or in that condition which is ordinarily styled typhoid, without presenting any characteristic symptoms, the only sign present to raise a suspicion of the true nature of the case being a cardiac bruit. The case is really one of blood poisoning or septicæmia, the source of the infection being, as it is supposed, in the heart, or in any place near the centre of circulation where ulceration and vegetations exist; but whether the septic material be decomposed fibrin, or the *debris* arising from the breach on the endocardium, or whether there be any distinct infectious substance circulating through the system, is still a question. For some years past it has been known that persons have died with symptoms of typhoid fever or pyæmia, and the necropsy has revealed the presence of fibrinous masses, or infarcts, in the spleen and kidneys, and that associated with these deposits there have been vegetations on the heart, usually of recent formation and situated on chronically diseased valves. Owing to the fact of one organ being especially selected for the manifestation of the infection, the inflammation attending it may be regarded as primary, and the real nature of the complaint overlooked. It is probable that in former years this mistake was constantly occurring. In one of my cases, probably owing to a plugging of some of the cerebral vessels, a meningitis was set up. In another case, the patient had empyema, and which, in spite of being treated by the best methods, seemed to be the cause of death; the autopsy, however, revealed an ulcerative endocarditis. When the symptoms are those only of blood poisoning, they are not always of the acute kind, but may continue over a course of several weeks and then put on the appearance of an intermittent fever. Again, a

patient suffering from known heart disease is attacked by febrile symptoms, pains in the joints, etc., and ultimately recovers. The case is regarded as one of subacute rheumatism, but it is truly one of blood poisoning, and the proof lies in the condition of the organs found after death. In the spleen and kidneys may be found infarcts of different ages, some recent, others drying up, and on the surface of the organs indentations and cicatrices indicative of the presence of much older deposits."

HYPERTROPHY OF THE HEART.

Dr. Samuel West recently exhibited to the Pathological Society, of London (*Lancet*), an hypertrophied heart from an ostler, aged 41, with the following rather peculiar history. He was well until three months before admission to the hospital. He then suffered from dyspnœa, pain and palpitation. The heart was found very large, no murmur, the arteries were hard, the lungs were emphysematous, and there was a small amount of albumen in the urine. Chronic Bright's disease was diagnosed. He became unconscious and died. At the autopsy the kidneys were congested, but otherwise healthy, no sclerosis. The heart weighed twenty ounces, was very large, slightly fatty, no disease of valves, and no cause of the hypertrophy, which was limited to the left ventricle, was found. It was, therefore, a case of cardiac hypertrophy without any of the usual causes being present. It also demonstrated how such a heart may break down without obvious reason. It was suggested that the coronary arteries did not increase in size in proportion to the increase in size of the heart, and so a point was reached where the blood supply was deficient and fatty degeneration ensued.

CORRESPONDENCE.

Medical Status in Cleveland, O.

ED. MED. AND SURG. REPORTER:—

Knowing that your readers are aware that the next session of the American Medical Association will be held in Cleveland, your correspondent thought you might not be averse to a letter from this point about the Profession, the Colleges and the Medical Institutions of this city.

At the present time such a task is an easy one. In fact, the prevailing subject of conversation and the greatest item of local interest is medical Colleges, Medical Graduates, and Professional Training. This subject has received impetus from the fact that two of the leading universities of Ohio—the University of Wooster and the Western Reserve University—have medical departments here, between which a peculiar controversy is waged. About a year since an effort was made to unite these two medical schools, and effect such a conjunction of their otherwise conflicting interests as would make one very large, well-supported institution, devoted to medical teaching. It is said that the two faculties met and selected a new corps of teachers—one-half from each school—and entered upon their new programme with well grounded hopes of succest. At first it seemed as if the consolidation would be approved by everybody, but opposition sprang up in an unexpected quarter; the Trustees of the University of Wooster, to the surprise of every one, announced most emphatically that at no time had they even contemplated the discontinuance of their medical school; that they had never authorized any action that could be construed as favoring such a step; and concluded by ordering the professors who had gone into the consolidation to return to their old position and resume their former duties. The professors, not putting in an appearance before the day set for opening the next session, the Trustees vacated their chairs and postponed the winter session of 1881-2 until the spring of 1882. This delay gave the Trustees time to organize the Faculty. Professors Firestone, Miller, Pomerene, Strong and Foote, of the former Faculty, remained. To this number the Trustees added Drs. F. J. Weed, J. E. Burns, T. A. Weed, Charles Arms, and L. B. Tuckerman, of Cleveland, and Dr. George Mitchell, of Mansfield. They also secured the services of Professor Xenophon C. Scott, formerly connected with the other College, who took the chair of Ophthalmology and Otology. Professors Reuben A. Vance and George Hunert, of Cincinnati, O., resigned their positions—the former in the Cincinnati College of Medicine and Surgery, the latter in Miami College—to take the chairs tendered them. Dr. Vance succeeded Dr. Gustav C. E. Weber as Professor of Operative Surgery and Clinical Surgery; Dr. Hunert took the chair formerly held by Dr. W. J. Scott—that of the Principles and Practice of Medicine and Clinical Medicine. The new Faculty sustained a heavy loss in the sudden death of Professor Joel Pomerene, an amiable and highly intelligent gentleman, whose early demise was mourned by a large circle of friends. The faculty, thus organized, began work the first week in March. Despite all the obstacles they had to contend against, the session was a successful one. The class numbered over forty. The graduating class embraced just twenty aspirants for a degree. The final examinations were written and continued through a whole week. A great outcry was raised so soon as the first day's questions were made public. It was claimed that the questions were unusually hard and that the examinations were unnecessarily severe. The excitement reached its highest pitch the beginning of the second week, when the Censors and Faculty reviewed the examination papers and announced that of the twenty would-be doctors seven had failed to attain the standard of proficiency established by the Trustees, Faculty and Censors. At the Commencement, Monday evening, July 3d, the Vice-Dean (Dr. Vance) announced that the position taken by the Faculty was one the medi-

cal profession had long been demanding; it was not assumed in fear and trembling, for the Faculty were so situated that the mere number of students they had in attendance was a minor consideration; and that it would be adhered to under all circumstances, for they were sure that there were enough earnest and sincere men in the profession standing ready to encourage such a departure in medical training to justify them in the step they were taking. The supporters and friends of the other college are divided in their views as to what the consequences will be. A number of them have no hesitation in saying that they think Wooster University has gone too far; that no medical college can be supported by its fees and make such demands of its students. To these gentlemen the outlook for Wooster is gloomy indeed. Another class argue that a high standard is desirable; these gentlemen are prone to speak in doubting tones of the advantage to the profession of a college which, out of a class of eighty, for instance, can send forth eighty doctors of medicine! They stand willing to support the institution that gives the best instruction and has the highest standard. There is no doubt, however, that the body of the profession here are pleased at the action of Wooster, and will support any college that will aid in checking the advent into their ranks of ignorant men, who look upon medicine as an easy trade at which to make money.

In addition to the two established regular Colleges, Cleveland can boast of two hospitals, the wards of which are open for Clinical teaching in Medicine, Surgery, and Obstetrics. These are Charity Hospital, under the control of the Medical Department of the University of Wooster, and the Cleveland City Hospital, managed by the Faculty of the Medical Department of the Western Reserve University. The surgical clinics at these institutions are especially interesting, and are held in amphitheatres arranged for such demonstrations. At the City Hospital, Professor Gustav C. E. Weber has charge of the surgical clinic, and his skill and reputation not only bring patients from all over the country, but are great attractions to students who throng there to hear him lecture. The Charity Hospital surgical clinic is held on Tuesdays and Fridays, by Dr. Reuben A. Vance. At this in stitution there are clinics of some kind every day. Here Professor X. C. Scott holds his eye and ear clinic; Dr. Miller, his gynæcological clinic, and Dr. Burns, his children's clinic. In fact, so far as facilities for clinical teaching are concerned, Cleveland stands first among the cities of the West.

Vigorous preparations are already being made to give the American Medical Association a cordial welcome here in 1883. Dr. X. C. Scott, the chairman of the Committee of Arrangements, is an indefatigable worker, and his efforts will be warmly seconded by every member of the Profession, not only in this city, but in the State of Ohio. The State Society appointed a committee to confer with the Committee of Arrangements, and upon separating, adjourned to meet here at the same time with the American Medical Association. It was suggested that the action of the Association in reference to the Minnesota State Society at St. Paul be a good precedent to follow in the case of the Ohio State Society at Cleveland. There the State Society met, transacted the necessary routine business, and then, at the request of the Association, adjourned, to enable its members to become "members, by invitation," of the latter. We anticipate a large attendance and a successful session. That many of the readers of the MEDICAL AND SURGICAL REPORTER will visit us next year, and that all will have a good time, is the sincere wish of

MEDICUS.

Cleveland, Ohio, July 7th, 1882.

The Causes of Labor Before and at Term.

ED. MED. AND SURG. REPORTER:—

Various reasons have been assigned, time and again, as to the causes of the onset of labor at term and before, but none have been altogether satisfactory. The theories have lacked practical demonstration. Now I have often thought carefully over the subject, and have finally come to the following conclusions:—

1st. In the event of the death of the fœtus before or at term, be it from either partial or total detachment of the placenta, or any other cause, it becomes a foreign body in the uterus, and as such acts as an irritant to the organ. Let us suppose that the placenta has become detached. The fœtus now loses its nourishment, the oxygenating blood and the development ceases. Acting as an irritant to the uterine walls, the impulse is conveyed by the nerve filaments to the ganglionic centre, whence it is reflected back to the uterus, the result being a contraction. Again, gestation having ceased the uterus is not called upon to expand or increase in size to any greater extent to accommodate its contents, and, therefore, obeys the impulse to regain its normal state and size.

2d. But suppose the fœtus to have reached full term? When the fœtus reaches the end of gestation, and the uterus is distended to its fullest capacity, what causes its expulsion? It is a well known fact that toward the end of pregnancy the fœtus becomes more and more restless than in the earlier months, and at term is not infrequently quite vigorous. The mother is capable of supplying all the oxygen necessary for the proper development of the child up to a late period, when it begins to clamor for more than she can supply: the heart, lungs, etc., have become fully devoloped and are now competent to perform their functions independently. Development has reached its height, and again, as in the case previously quoted, the fœtus becomes a foreign body. Irritation is set up by the strong movements, and by the same process contraction is induced. In the one case labor is brought on by the useless presence of a dead child irritating the nerve centres; in the other, by a living child, by its restlessness or by encroaching on the uterine walls, doing precisely the same thing.

When the apple is ripe it drops from the tree; it does so because it has reached its maturity and further nourishment is no longer possible nor required. The chick emerges from its shell, it having become fully developed, and, in fact, not

receiving any more nourishment craves for more. The leaf drops from the bough, the sap taking another course after performing its duty. Every thing, animate and inanimate, bows before nature's law of self-limitation.

Philad'a. ANDREW L. WITTKAMP, M.D.

Regular Medicine.

ED. MED. AND SURG. REPORTER:—

At the recent meeting of the Oregon State Medical Society the following resolutions were offered, but not adopted:—

Resolved, That we consider the practice of regular medicine consists, as far as therapeutics are concerned, in the use of every drug, medicine, method, ism or pathy known or supposed to possess curative virtues. "The whole unbounded continent" of remedies is ours, and we are not bound or restricted in our use of any curative measure, or to any exclusive method or medical doctrine.

Resolved, That we do not consider it a violation of medical ethics to consent to assist a patient under the care of a hydropath, homœopath or any other practitioner of a one idea plan of treatment; but should consider any regular physician very imperfectly qualified for his profession, if he ever required the assistance of any of the pathists or irregulars in his management of patients. C. H. M.

Removal of a Myo-fibromatous Tumor.

ED. MED. AND SURG. REPORTER.

Some few months ago I was consulted by Miss Dennis, aged thirty, medium stature, who informed me that she had had a bloody flux from the vagina for the past four years, and during the menstrual epochs the flow had been alarming, with an accompanying dysmenorrhœa, which anodynes failed to alleviate. Several physicians, including a gynecologist, advised her to be patient, as she was undergoing the ordeal of "change of life," and in due time she would be well. From the history of the case, I suspected that I had to deal with an intra-uterine tumor. My patient was at this time exsanguinated, dyspeptic, and anasarcous, in a word, bed-ridden, from pain and exhaustion. At the first vaginal examination nothing of note was revealed, save the bloodless hue of the parts. Unable to manipulate with the uterine sound, owing to stenosis, I at once instituted gradual dilatation of the cervix uteri, in order to search for the disease that was rapidly terminating the life of my patient. She was ordered to be kept at absolute rest, in the recumbent posture, her diet to be nutritious, with ferruginous tonics, and the vagina to be tightly and constantly plugged by tampon.

During the following month I succeeded in dilating the cervix to admit the index finger, when I encountered, with the aid of the uterine sound, a growth encapsuled within the fundus and the posterior uterine wall. By the use of the therapeutic measures named a status of health was reached that justified operative procedures. With the assistance of Dr. E. P. Irons and my student, Mr. Abbott, I proceeded to remove the tumor, after the mode described by Prof. T. Gaillard Thomas in his great work on gynecology (p. 544). My assurance of success was abundant, having at command Prof. Thomas' spoon-saw, my "sheet anchor" in the surgical handiwork. In one hour I was rewarded with the privilege of presenting to the friends of my patient the entire tumor, weighing one pound and three-quarters.

By the hypodermic use of the bi-muriate of quinia for a few days, the temperature was kept within the bounds of safety. In one month from the date of operation her convalescence was speeding into recovery. At the time of writing she is enjoying excellent health, being free from discomfort of every kind.

Baltimore, Md. G. GLANVILLE RUSH.

A Mistaken Diagnosis.

ED. MED. AND SURG. REPORTER:—

A case of sickness occurred twelve miles from Fort Worth, Texas. A country physician in attendance was asked if the case was not one of smallpox. He, in reply, stated no, that the case was one of extraordinary interest, and without parallel in his whole reading or personal experience. Further, that he would wager that, should Dr. A., B. or C. be called from Fort Worth they would corroborate his diagnosis, which was that the man had "erysipelas from the toes to the knees, measles from the knees to the waist, and seven years' itch from the waist to the top of the head. An intelligent physician being called in readily diagnosed confluent, smallpox. The sequel proved the correctness of the last diagnosis, as several persons contracted the disease. The first physician, to the credit of Texas, is not a native. The last was.

Fort Worth, Texas. VERITAS.

NEWS AND MISCELLANY.

Singular Legacy to the French Government.

M. Giffard, the well known Parisian inventor of balloons, who died some time ago, has left a legacy to the French Government, under the most singular conditions. He desires that it be devoted to the establishment of *suicidaria*, or national institutions in which persons suffering from painful and incurable diseases may be allowed, by the use of chloroform and other such agents, to shorten their own existences, acting under the direction of medical experts, and with the consent of their friends. M. Giffard secured a euthanasia for himself by a special apparatus he invented for the inhalation of chloroform. M. Renaud has joined the movement for the promotion of painless suicide in France, his only stipulation being that no man shall, by law, be entitled to take his own life, until he has obtained the consent of his friends in what is known as the *conseil de familie*.

The Late Sir John Rose Cormack.

At a meeting of the friends of the late Sir John Rose Cormack, at the house of Dr. Semple, it was decided to organize a committee for the purpose of raising a fund for the benefit of Sir John's family, for notwithstanding the devotion of a long and laborious life to his profession, he has died without leaving any provision for his widow and children. A committee for the same purpose has already been formed in Paris, and subscriptions have been forwarded to that quarter. The London committee consists of Sir J. Risdon Bennett, Dr. Quain, Dr. A. P. Stewart, Dr. B. W. Richardson, Mr. W. H. Michael, Q.C., Dr. Thudichum, Dr. McIntyre, Dr. Semple, and Dr. A. Henry, Secretary. Dr. Semple was appointed Chairman of the Committee, and Dr. B. W. Richardson, Treasurer.

Items.

—Dr. George Elder, resident surgeon at the General Hospital, Nottingham, England, has, we understand, just performed nephrectomy for scrofulous disease.

—The Boylston Prize Essay given by Harvard University has been obtained by Th. M. Dolan, F.R.C.S. ED., Halifax, Yorkshire; value of prize $300, the subject of the essay being "Sewer Gas."

—A whole family, consisting of six persons, living at Murceaux, in the Department of the Seine-et-Oise, have been poisoned through eating poisonous fungi in mistake for mushrooms. Medical aid was sought, but to no avail, and all six died in great agony.

—Dr. Robert Koch, accompanied by Dr. Struck, the Director of the Imperial Board of Health at Berlin, had an audience of the Emperor on June 5, when he explained to his Imperial Majesty the results of his investigations on tubercle, and demonstrated his preparation containing the bacillus of that disease.

—Malarious fever, in an epidemic form, has of late been very fatal in the Mauritius. During April alone, there were no fewer than five hundred and ninety-six deaths, and these, unhappily, included some of the prominent officials of the island. The death rate from fever has been higher than in the previous five years.

—During the last fifteen months, as many as two millions of persons have been vaccinated and revaccinated in the State of Illinois. To this general vaccination is undoubtedly due the small progress that smallpox has of late made in the State—the disease having been, in the majority of cases confined to those first attacked.

—In his cross-examination of the surgeon, the lawyer said that a doctor ought to be able to give an opinion without making a mistake. The surgeon replied, "They are as capable as lawyers." The lawyer said, "A doctor's mistakes are buried six feet under the ground, a lawyer's are not." "No," said the surgeon, "but they are sometimes hung as many feet above ground."

OBITUARY NOTICES.

DR. ALFRED M. SLOCUM.

Dr. Alfred M. Slocum died June 21st, after a brief illness. He was born in Germantown, Philadelphia, December 2, 1822. He studied medicine, and graduated from the University of Pennsylvania in 1847. He was a skillful and thoroughly conscientious physician, but so modest and retiring that his abilities were, perhaps, not as widely understood and appreciated as they should have been. His life record was written in deeds. For one year after leaving the University he was physician at the Wills Hospital. For six years he was resident physician at the Northern Dispensary.

He was, for ten years, visiting physician at the Episcopal Hospital, and for sixteen years at the House of Refuge. He was also visiting physician at the Charity Hospital and the Magdalen Society.

As a member of the Philadelphia College of Physicians and the County Medical Society, he was esteemed by his fellows, and respected alike for his talents and his unvarying courtesy.

Dr. Slocum was never a robust man, and suffered, at times, from disease of the heart; this chronic trouble doubtless being the cause of death. He was a member of St. Philip's Episcopal Church, a true Christian, and an affectionate husband and father.

QUERIES AND REPLIES.

J. C. W.—For the skin troubles arising from poisoning by poison ivy you may use fl. ext. grindelia robusta, f℥ij to f℥iv of water, as a lotion, also a saturated solution of hyposulphite of soda. Sulphate of zinc is also good, a few grains to the ounce.

A and B.—B's conscience must be his guide. If he did nothing and said nothing to lessen the confidence of the patient, his family or friends, in A, and acted in every particular strictly in accordance with the ethics governing consultations, then he can and ought to accept the call to treat the case.

MARRIAGES.

ADAMS—SMITH—At the home of the bride, Berwick, Pa., June 15th, by the Rev. A. B. Smith, brother of the bride, assisted by the Rev. W. W. Evans, A.M., Mr. Louis J. Adams, M.D., of Evansville, Pa., and Miss Clara V. Smith.

BOTKIN—HAUCHER—At Claysville, by the Rev. A. A. Mealey, assisted by Rev. J. L. Leeper, Dr. L. C. Botkin, of Burgettstown, Pa., and Miss Annie C. Haucher, of Claysville, Pa.

CHALFANT—WEBSTER—June 14th, 1882, by Rev. J A. Cook, in the Presbyterian church of Jewett, Ohio, Dr. Robert W. Chalfant, of Logan county, O., and Miss Maggie Webster, of Jewett, Harrison Co., O.

FERGUSON—CAMPBELL—On Wednesday, June 7th, 1882, at the residence of the bride's parents, by Rev. Gracey Ferguson, William Ferguson, M.D., and Mrs. Annie K. Campbell, daughter of John Kitchenman, both of Philadelphia.

DEATHS.

GOLD—In this city, on the 12th of June, Hiram Gold, M.D., in the 49th year of his age.

SLOCUM—In this city, on the 21st of June, Alfred M. Slocum, M.D., in the 60th year of his age.

TREVOR—In this city, on the 13th of June, Dr. M. R. Trevor, of paralysis.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

PRACTICAL NOTES ON THE DIAGNOSIS AND TREATMENT OF ULCERS.

BY G. HALSTED BOYLAND, A.M., M.D., ETC.

Of the greatest importance is the classification of ulcers into such as owe their origin entirely, or at least essentially, to local causes—local idiopathic ulcers, and such as spring from inner constitutional causes—constitutional, dyscrasic, symptomatic ulcers. Those ulcers most frequently met with in general practice are the ones which will occupy attention in this article. They are: scrofulous, syphilitic and scorbutic.

Scrofulous Ulcers.—These originate, in the great majority of cases, in the direction from within out, notably from suppurating lymph glands and from bones in a state of chronic inflammation or ulceration; again, from cold abscesses that have broken outwardly; in some cases also from superficial pustules, generally in childhood; they get better in autumn and worse in spring; recur frequently, even after an apparent perfect cure—this likewise mostly in the spring. Their ground is pale and unclean, their borders lax, quite ordinarily undermined (sinuous ulcers) more especially in such as go out from lymph-glands or bones; the surrounding parts are livid, the secretion thin-flowing, mixed with cheesy flakes, often also cheesy in its entire consistency, in which case it is usually of tubercular character. Healing takes place very slowly, indeed, even with the best local and general treatment; cicatrization always begins only after the undermined borders have been removed, either by spontaneous necrosis or by the aid of art. The scar has a rayed and shining construction, and is therefore not unfrequently compared to the appearance of frost upon a window pane. This depends materially upon its long development and the greatness of the loss of substance, but not upon the specific influences of the scrofulous dyscrasia. The other characteristic appearances of habitus scrofulosus are always well marked in these cases.

Syphilitic Ulcers—Chancres.—These appear either as the direct local consequence of inoculation with syphilitic contagium, or as symptoms of the general affection caused by any manner of transmission of this contagium—lues syphilitica, constitutional syphilis. In the first case they are called primary, in the second, secondary ulcers. The primary syphilitic ulcers mostly locate themselves according to the infection, sometimes on the lips of the mouth, usually on the genitals, and under three essentially different forms, to wit: simple, soft chancre; indurated, infectious chancre and phagedænic chancre.

The simple, soft chancre has a round form, an even ground, a sharp-cut border, as if made with a punch, rolled a little outward and slightly undermined; the secretion is unproportionately rich, thick, of a whitish yellow or yellowish green color, and in the highest degree infectious. The surroundings and the ground of the ulcer remain in the normal state of tissue and are, as a rule, free from induration. Nevertheless, cases do happen, in which, partly after the exhibition of medicines, partly also without them, a hardening in the ground of the ulcer takes place,

which we designate as inflammatory, and which, in point of fact, does not differ from other processes of inflammatory induration. Soft chancres are found several together on the same individual oftener than one single one, as they either appear at once, three or four in number, or increase gradually by local infection from one original ulcer. Swelling of the lymphatic glands belonging to the diseased side, mostly the inguinal glands (buboes in strict sense) can sooner or later complicate soft chancre, but are much more frequently absent. When they do come, they remain almost always upon the diseased side of the body, are limited to the superficial glands, and can as easily end in discussion as in suppuration. In the latter case, after the glandular abscess has broken, simple cicatrization or ulceration follows. Cicatrization may then be expected when the abscess had its seat, not in the gland itself, but in the peri-glandular connective tissue. If ulceration of a bubo occurs the secretion is again contagious. Inoculations with the pus of such a bubo or of a soft chancre have always brought about the development of a soft chancre, even when made a thousand times on the same individual. Whenever the inoculation is repeated a soft chancre always comes again, immediately, and without a period of incubation. On the soon reddened point of inoculation, and within the first twenty-four hours, an inflammatory speck is developed, on the summit of which a small pustule filled with water, clear liquid, is formed by pushing up the epidermis.

Its contents become gradually turbid, until the third day, when it already attains the size of a pea, and sinks like a navel in the middle. Often this itching pustule is intentionally disturbed or destroyed by chance, in scratching; otherwise it finally bursts and leaves, generally between the seventh and tenth days after inoculation, the ulcer that has developed underneath, with the above-mentioned characteristics. Seldomer the pus-like contents dry in, and a brown crust is formed, that sits fast upon the ulcer, without causing it otherwise to differ from the nature of soft chancres. In its further course the ulcer grows, retaining its round form, at times more at others less in the surface, and thus sometimes neighboring ulcers run together. In most cases the granulations going out from the ground of these ulcers are not idle; often such flesh papulæ grow up too rankly, so that an ulcus fungosum is developed, that can have pathological anatomical resemblance to broad condyloma. Generally, however, unless the ulcer assumes a phagedænic form, cicatrization follows within several weeks, and without surgical or medical interference. When this begins the secretion of the chancre sometimes ceases to be infectious: but often it retains its power of contagion until cicatrization is ended.

The indurated or infecting chancre is much rarer than the soft chancre, and appears, in most cases, one alone, in parts of the body suited to it. Its form corresponds, as a rule, to that of the soft chancre; but the entire surface of the ulcer appears smooth, varnished like, the ground fatty, whitish-gray colored, and darkly pointed in the middle. The somewhat erect borders are not undermined, the secretion is much more sparse, and much more like good pus than in the first kind of syphilitic ulcers. In accordance with the name, the ground and surrounding of an indurated chancre exhibit a remarkable cartilaginous hardness, which mostly extends to a considerable depth, seldom remains confined to the superficial layers, and still seldomer surrounds the ulcer in a circle. This induration is distinguished from the before mentioned inflammatory one by the absence of redness and pain; on the other hand, it is customary to find diminished sensibility in the hardened parts. In the corresponding lymph glands is regularly developed, within the first fourteen days after the appearance of the chancre, a painless, above all not inflammatory swelling, and therefore, in the beginning, always without participation of the peri-glandular tissue, from which, mostly after some time, the analogous glands of the other side are also affected, even though less severely. These so-called indolent buboes form very nodulated tumors, corresponding in quantity to the number of the diseased glands. They last, as a rule, much longer than the chancre that produced them. By direct attack, and by great exertion, inflammation, and then suppuration, with consecutive breaking out, can be brought about in them.

In scrofulous subjects this happens very easily and often without any apparent cause. Inoculation with the pus of an indurated chancre or from the bubo depending upon it, on the same body, which is already or was affected by ulcers of this kind, is never followed by any result. If this transmission, on the other hand, takes place for the first time, either intentionally or by accident, the secretion of the indurated chancre proves to be decidedly contagious. After an incubation period, of from two to six weeks, a pimple-like knot appears, which soon begins to ulcerate from the middle to the circumference, and without much pain, at times quite unnoticed, changes into the character-

istic ulcer. The further course until the, also in this case possible, cicatrization of the ulcer without the aid of medicine or surgery, lasts from four to six weeks; this takes place, at first, by the shooting out of good granulations from the border, and goes on generally in centripetal direction, seldom equally over the whole surface. Exceptionally the growing ulcer-granulations change into broad condyloma. The induration remains, as a rule, after cicatrization, sometimes only a few weeks, sometimes for years, and then gradually disappears. If the chancre had its seat in the outer skin, the scar then retains often still longer a characteristic, dark color, that is never observed after a soft chancre. The distinction between these two different kinds of syphilitic ulcers, after the above given description, will present no especial difficulties. It is, however, essential and necessary, because in soft chancre it is a question of a malady that very seldom, perhaps never, is followed by disease of the rest of the body; whereas, constitutional syphilis not only follows with great certainty an indurated chancre, but also appears already during the incubation period of the ulcer to develop itself with it, so that we may, with more right, regard the induration as first symptom of the general affection than the direct effect of local transmission.

Phagedœnic chancre is such an one as appears with gangrenous disturbance spread widely around it. Phagedœnic chancre presents in a wide surrounding inflammatory and œdematous swelling, its ulcerous grounds showing a resemblance to the diphtheritic coating that is seen in hospital gangrene. This character, which in every respect offers analogies to nosocomial gangrene, is ordinarily first assumed after the chancre has existed already for some time, much oftener in soft than in indurated ulcers, and is to be regarded as a complication, which it is true must be especially described, but by no means justifies us in designating it as a distinct species. All that will be said with reference to the contagiousness of the secretion, the rarity of a general affection, the kind of buboes, and so forth, in speaking of phagedœnic chancres, finds its explanation in the fact that most soft chancres are subject to this complication. The at times more ulcerous, at others more gangrenous disturbance—the latter also designated as gangrenous chancre—spreads itself more along the surface than in the depths, quickest in connective tissue, next to that in the skin, with less facility in other tissues.

The shape of the ulcer is usually irregular and serrated, the border sinuous, often widely undermined. Healing of this extended disturbance takes place the more slowly because mostly weakened or otherwise diseased individuals are subject to this complication.

Secondary syphilitic ulcers develop themselves on different parts of the body; at times on the mucous membranes, at others on the outer skin. In the first case the mucous membranes of the palate and pharynx are the seat usually preferred. On the outer skin appear the most forms of syphilitic exanthema, the so-called syphiloids, now pustules—ecthyma, then blisters—pemphigus, rupia; again tubercles, etc. Or there are buboes that have broken out, or syphilitic gummy tumors, finally inflamed bones and caries. The last two symptoms may more properly be designated as tertiary ulcers, as it is customary to regard the local diseases out of which they spring as a tertiary condition. With more probability is the indurated chancre already classed by us in the primary ulcers, certainly, at least, its characteristic induration, to be regarded as *secondary;* that is, as a breaking out of the already developed general disease. As manifold as the forms of syphilitic exanthema, are also those of secondary ulcers; nevertheless, the serpiginous type seems to be more generally selected. But it is utterly impossible out of the form and appearance alone, to determine with certainty the syphilitic nature of such an ulcer; on the contrary, the history of the ulcer itself, and the condition of the whole surface of the patient's body, especially the presence of any eruption, the continuance of induration on places of first infection, the swelling of the lymph glands, and finally, the anamnesis in its widest sense, must aid us in fixing a diagnosis. Perfect certainty is often arrived at only *ex purantibus et nocentibus.*

Scorbutic ulcers are caused by reason of faulty nature of food generally, favored by long exposure at the same time to moist air. These are the results of a general disease, being brought out directly by effusions of blood in and under the skin, with lively pains, on the thigh, the external and internal gums. Their ground is nodulated, unclean, usually of a bluish-red color, as the tissues, becoming necrotic, are infiltrated with half coagulated blood. The border is loose, and, like the surrounding of the ulcer, often œdematous and filled up with blood; sometimes loose, easily bleeding granulations grow up out of it. The secretion is very thin, mostly tinged with blood, and of a disagreeable, sweetish odor; the remaining scars are livid and shining.

Lupus.—The ulcerative form of lupus is more common than the exfoliative or serpiginous. After the primary appearances (pustules, small knots or spots) have existed for some time, they multiply, either with inflammatory symptoms, or the diseased skin or mucous membrane becomes covered with a diffuse redness, swells also by œdema, and here and there the thin epithelial layer is broken through. The, at first, small, round, very little or not at all painful ulcers spread themselves, either in breadth or depth, run into each other from all sides, and then get irregular, serrated borders. They become covered with brown, fast adhering crusts, under which a yellowish, thick, or brownish, thin mass is continually forming. If these crusts, which are generally dried fast on and in layers one above the other, be removed, bleeding easily follows from where they sat, from the hyperæmic, weeping borders of the ulcer. The crusts always gain in thickness as the depth of the ulceration increases, until, as for instance on the nose, not only the skin and muscles, but also the cartilage and bones are attacked. The superficial lupus, as also the deeper, can cicatrize spontaneously, by diminution of the hyperæmic tendency. The scars are the scars of gangrene ; white, more or less elevated, folded strings, with great inclination to shortening. Often they break out afresh, when the pustules or knots in the periphery ulcerate. From many sides, and with right, the resemblance of lupus to syphilitic disease is dwelt upon. With lupus there is very frequently scrofulous diathesis. According to Cazeneuve, the small knots and tubercles that form under the influence of a syphilitic dyscrasia are more voluminous, rounded, and have the above-mentioned dark (copper-red) color; they are not, like those of lupus, covered with whitish epidermic scales, continually pushing each other off. The syphilitic tubercle usually is found in older individuals ; on the other hand, lupus selects childhood and youth. Ulcerating, syphilitic tubercles have swollen, reddened, zigzag borders. They spread in depth or on the sides, in sinuous pockets, and cause, in course of ulceration, fistulous passages under the skin ; while the ulceration of lupus always begins on the surface, and with this, makes its appearance much earlier than that of syphilitic tubercle. The neighboring bones, *e. g.*, the inferior maxillary, ossa nasalia, are, in lupus, only laid bare, so that they may be seen in the ground of the ulcer, without apparent change, while syphilitic ulceration attacks them. Beyond these, the other pathological conditions of the body caused by syphilis offer always distinguishing features. In many cases the distinction is possible from these alone.

Treatment of Ulcers.—If the ulcer rests upon a dyscrasia, this must be removed. Undoubtedly the therapy of dyscrasia belongs essentially to the field of inner medicine. Therefore, in this place it will only be regarded in so far as it may have reference, in helcology, to the most salient dyscrasic affections—scrofula, syphilis and scurvy. The most important point in the treatment of scrofula is to procure for the patient easily digestible, nourishing food, and to keep him in pure, warm air. Only when these conditions can be fulfilled is help to be afterwards expected from the untold number of drugs recommended. Among these the most seem to have for their only object an increase of the general nourishing. In this view is recommended in very large quantities and only in very large quantities continued for some time, cod-liver oil, phosphate of lime, preparations of iron, and the so-called bitter medicines, which last, perhaps, only work by increasing or regulating the appetite.

From another list of medicines is expected a specific change in the general process of nutrition. Here belong, particularly, the preparations of iodine, antimonials, salt baths, whose percentage of iodine and bromine is also brought into consideration. While the pharmaceutical preparations of iodine and antimony are followed by doubtful results, in so far as they are not confined to very small doses, and are used even not without danger ; there is only one voice as regards salt baths (natural and artificial). Undoubtedly their greatest efficacy consists principally in enlivening the skin. Frequent baths in general, with good diet, should be ordered.

In the treatment of syphilitic ulcers we must start on the hypothesis that, through every primary ulcer, perhaps, a general infection will follow ; the removal, then, at the earliest possible moment, of the infecting ulcer (chancre) is strongly urged as a prophylactic measure against constitutional disease. The newly grown or still developing primary chancre must be thoroughly cauterized. The choice of caustics is not, indeed, of so much consequence as is claimed by many authors ; and yet caustic potash, Vienna paste and chloride of zinc, on account of their fundamental workings, are preferable to nitrate of silver (lapis). This prophylactic cauterization must appear foolish to those who hold it proven that soft chancres have never secondary consequences, and are only a harmless local affection ; and that the indurated chancre already belongs to

secondary syphilis. In the first instance, cauterization would be of no use; in the last, alike useless, because "too late." But as long as the correctness of this opinion, held by us also as highly probable, remains doubtful, it is the duty of the practitioner to advise cauterization for all fresh chancres. And even if in hard chancre it is never possible to entirely destroy the poisonous, infectious matter, in loco, before its reception into the circulation, juices and tissue, it is, nevertheless, probable that its intensity may be modified by cauterization. However, an anti-dyscrasic treatment is indicated upon the appearance of induration, which need not necessarily be carried out in soft chancres, unless secondary symptoms show themselves. In phagedænic chancre the mercurial treatment was formerly warned against, as physicians thought it necessary to commence an anti-dyscrasic therapy in all cases of chancre, on the ground that the destruction of tissue was thereby hastened. As phagedænic chancres are almost always soft, reason for such a treatment seldom exists. Bardeleben* has never (after an extended experience) seen such injurious results from the internal employment of sublimate; and states further, "according to the analogy, the contrary should be expected, as sublimate, administered internally, in hospital gangrene, is recommended by the best authorities, as v. Pitha." The local treatment of phagedænic chancre forms part of that of hospital gangrene, while the ordinary chancre is treated essentially as an asthenic ulcer.

SICK HEADACHE; ITS CAUSE, HYPERMETROPIA AND ASTIGMATISM, EITHER ALONE OR COMBINED, AND ITS CURE, A PROPERLY FITTED GLASS.

BY G. C. SAVAGE, M.D.,
Of Jackson, Tenn.

In this article I propose to make known to the medical profession my discovery of the real cause and the successful treatment of sick head ache, that opprobrium of medical art from the beginning down to the present time. I shall give the circumstance that led me to the discovery, and shall offer arguments to convince others of the correctness of my conclusions.

One has said: "Headache destroys much of the happiness and cheerfulness of life, and reduces many a highly gifted and poetical soul to the level of a discontented drudge." This language is doubly applicable to sick headache, that dreadful disease which makes youth look forward to old age with a feeling of delight, and long for its approach, when, as he has been told, his malady will disappear.

I, for years, had been a sufferer from sick headache, and after becoming a member of the medical profession, sought from all sources a cure for my malady, but found none. I believed the teaching of authors as to the cause of the disease, viz., stomachal trouble, and took almost every remedy recommended, but continued to have attacks of greater or less severity every month, frequently twice a month. Finally I gave myself over to what I considered my unalterable fate, and thought of nothing as a cure for my disease but old age, and consequently, when suffering, would almost have a secret longing to be old, that I might be free. I had often wondered why it was that old age gave immunity, and turned in vain to authorities to find a satisfactory reason.

The Circumstances Leading to my Discovery.—My mother, from whom I supposed I had inherited my predisposition to sick headache, was a great sufferer from the same malady. I had seen her confined to her bed, frequently as long as three days, suffering almost as much as mortal could bear. She lived and suffered until age gave her ease. From 45 to 50 her attacks were less frequent and not so severe. She has had but few attacks since 50, and now, at the age of 58 years, she is entirely free from attacks, and has been so for several years.

During the last few years she has noticed that she cannot distinguish persons or things at a distance, as she once could, but she supposed that this was one of the natural consequences of age. She did not think about her freedom from sick headache having been purchased at the sacrifice of perfect distant vision.

In January of this year (1882) she visited me and spoke of the failure of her vision for distant objects. (Long ago she had commenced the use of glasses to correct her presbyopia). Hoping that I might be able to make her see better, I asked her to go into my office with me, where I could test her vision. I found the vision of her right equal to $\frac{20}{c}$, *i. e.*, at a distance of twenty feet from the card she could see only letters that a perfect eye could see at a distance of one hundred feet; while vision for left eye was equal to $\frac{20}{lxx}$. Her once latent hypermetropia had been converted, by loss of power in her ciliary muscle, into a wholly manifest hypermetropia, no astigmatism existing in her case. A spherical convex glass

of 24 inches focal distance gave her perfect vision in right eye, and a similar glass of 36 inches focal distance gave perfect vision in left eye. On questioning her a little the thought entered my mind, could not her far-sightedness have been the predisposing cause of her sick headache, and would not the simple glasses I now give her, if they had been given her in early life, have transformed her years of suffering into years of ease? This thought dominated me, and I went about the inquiry in earnest.

The books all say that age gives immunity; and knowing that age always converts a latent into a manifest hypermetropia, I at once sought out other old persons who from youth to age had been sufferers from sick headache, that I might see if they too were hypermetropes. I failed to find one who did not have manifest hypermetropia, and whose bad sight for distant objects did not come on as the sick headache disappeared.

The doctors with whom I have talked all say they do not know an instance in which sick headache did not give way between the forty-fifth and sixtieth years of age, but they can make no statement as to vision, whether it was good or bad.

In the meantime I continued to suffer. During January, February, and March, of the present year, I had a number of attacks of sick headache, perhaps as many as six. I know they were very frequent, and occasionally very severe. The more I used my eyes in reading and writing, the worse were my attacks. My investigations had led me to believe that hypermetropia is the cause of most, if not all, cases of sick headache (that form continuing through life, regardless of old age, if sick headache at all, must be due to some other cause), and I was only waiting for time to test my opinion, in my own case. In the latter part of March, of the present year, the premonitory symptoms of an attack of sick headache warned me of the ordeal through which I must soon pass, unless something could be done to avert it. I did not take the accustomed dose of chloride of sodium, which always gave me as much relief as anything I had ever taken; but had three or four drops of a one per cent. solution of atropia put in my left eye, the one always hurting me throughout an attack, my headache and eye-ache being confined to the left side. In half an hour my ciliary muscle was at rest, and I was perfectly free from pain and had no inclination to vomit, whereas, if the atropia had not been put in my eye, by the end of the same half-hour my headache would have been almost unbearable, and great nausea and vomiting would have attended, all to last and make me most miserable for several hours. I was most happy with the change I had experienced, and felt like crying out, "*Eureka!*" What gave me relief? The atropia had relieved the tension of the ciliary muscle, putting it at rest, and thus relieving its pain; and, there being no further cause for sympathy on the part of the head and stomach, the pain and nausea ceased. Although I had, apparently, perfect vision before the ciliary muscle was put at rest, I now found my vision equal to $\frac{20}{c}$, *i. e.*, I could see at a distance of twenty feet only letters that, before the atropia was used, when the ciliary muscle had its full power, I could have read at a distance of one hundred feet, and even these large letters seemed double. Now the condition of my ciliary muscle under atropia is just the condition natural and essential to a perfect (emmetropic) eye, when looking at distant objects, and yet the vision of an emmetropic eye would be equal to $\frac{20}{xx}$. Both hypermetropia and astigmatism existed in my eye, already at rest, for which I gave the full and proper correction. The glass correcting the defect and enabling me to see without straining, as well as a perfect eye can see, is a combination of a convex spherical of forty-two inches focal distance and a convex cylindrical of sixty inches focal distance, with its axis set at an angle of 95°. I afterwards found my right eye both hypermetropic and astigmatic, and gave it the proper correction. Since March I have been doing all my reading and writing with my glasses, with the exception of one week, and for laying them aside for only that short time, I paid dearly in suffering from a severe attack of sick headache. The reason for laying them aside was twofold, viz: 1st. I was using the heavy glasses and still heavier frames of my refracting case, which, on account of their weight, were uncomfortable; and 2d. I wanted to test their value by not using them. While wearing them I did not feel a single symptom of sick headache. When I put them off I continued reading and writing as when using them, but with inconvenience I had never felt before. I suffered so from the attack of sick headache caused by the disuse of my glasses I shall never repeat the folly in the future. I had a pair of spectacles made, and now wear them all the time, and feel that I am safe from attacks relief from which I had expected nothing but age to give me.

In my own case sick headache had its cause in hypermetropia and astigmatism, and its cure was glasses.

I have had but one other case by which I have been able to still further demonstrate the correctness of my views. That case is a married lady, twenty-six years of age, a sister of mine. She was not so great a sufferer as either our mother or myself, but her cure has been as perfect and remarkable as my own. She was hypermetropic in one eye, and both hypermetropic and astigmatic in the other eye. The proper glass for each eye was given her, and now her sick headache is a thing of the past.

Since writing the above, my preceptor, Dr. Crook, of Henderson, this State, came into my office, to whom I made known my views. He is one of the many sufferers from sick headache, and like all others, believed the predisposing cause some stomachal trouble. He said, "can hypermetropia be the cause in my case? I always thought I had perfect sight." I told him that, according to my theory, it was, and that I had no doubt but it was. I asked him to let me test his vision and see. We selected his right eye, that being the one he suffers more from. Before instilling the solution of atropia I determined, by means of a convex glass, that he was hypermetropic, though without the glass his vision was equal to $\frac{20}{xx}$, his hypermetropia being latent. Atropia converted his latent into a manifest hypermetropia, and now, instead of his vision being $\frac{20}{xx}$, it was not more than a perfect $\frac{20}{c}$. A spherical convex glass of twenty-four inches focal distance gave him perfect vision. He was surprised, but now believes, with me, that properly fitted glasses for both eyes will do for him what my glasses have done for me, cure his sick headache. This case is another link in the chain of evidence that will, when complete, convince all of the correctness of my views herein set forth.

This is the first of my making public my discovery, and, lest I might be too severely attacked by some one, I will produce some arguments to support my views.

Flint, in his work on Practice, says that the affection involves a constitutional predisposition, acting with which, various exciting causes may bring on an attack. He could not name the predisposing cause. He supposed that some toxical agent must exist in the blood, but says its source and nature are unknown. I claim that the predisposing cause is hypermetropia and astigmatism, either alone or combined, and that chief among the exciting causes is work requiring the convergence of the axes of the eyes with the attending action of the ciliary muscle, such work as reading, writing, sewing, crocheting, etc., which work, in an emmetropic eye, would produce no bad symptoms.

With Flint I agree that the predisposition, in most persons, ceases at the age of 50 or 60 years. While he gives no reason, to me there is a satisfactory reason, and it is the only one ever offered, so far as I know, it always having been considered an unexplainable fact. My explanation is that it is about the age of 50 or 60 years, in most persons who are hypermetropic, whether they suffer from sick headache or not, when a latent hypermetropia is converted into a manifest hypermetropia, the ciliary muscle that has had to work so hard during so many years being worn out and ceasing its labors. Long before this has presbyopia (old sight) come on, requiring the person to use spectacles when doing near work, as reading, etc. By this time the hypermetropia is manifest, while during the period through which he suffered, perhaps 30 years or more, the hypermetropia was latent, rendered so by the action of the ciliary muscle.

The periodicity of the attacks may be explained by the eye's being able to bear for a time the excessive work which it is made to do, when at length its distress is made known by an explosive attack of sick headache, the eye and head aching indescribably and the stomach, through sympathy, so desperately nauseated as to unload itself of its contents. Even before the attack comes on the stomach performs its functions sluggishly, through sympathy for the overworked eye. Cannot the stomach sympathize with the eye if the eye and head can sympathize with the stomach?

To Flint's next statement I am not ready to give my assent, viz., that the predisposition exists more frequently in females than in males. We may take one hundred females and one hundred males out of the same city, town or neighborhood, and I doubt if we find more hypermetropes (hypermetropia, according to my theory, being the predisposing cause) among the former than among the latter; but, at the same time, I believe that the number of females actually suffering from sick headache would be much greater than the number of males. Why? Perhaps seventy-five out of the one hundred females would have to employ many hours in the day in reading, sewing, crocheting, or some kind of work requiring near vision, with the necessary tension of the ciliary muscle, the one great exciting cause of sick headache; while not more than twenty-five of the one hundred men would be engaged in work requiring continuous near vision. Then, while I do not know that the pre-

disposing cause exists more frequently in females than in males, yet I believe that I am right in concluding that the former are more exposed than the latter to the one great exciting cause mentioned above.

The clinical history of sick headache given by Wood in his Practice, is unobjectionable. But when he says that the predisposition, for the most part, consists in debility of the stomach, and a peculiar state of the nervous system which renders the brain especially sensible to gastric irritation, I must dissent from, though I once embraced, the doctrine, and drugged myself accordingly. In most cases he thought the headache secondary to the stomach affection, the head sympathizing with the stomach; but says there is reason to believe that the reverse is sometimes the case, the head affection being primary, the stomach trouble secondary, the stomach in this case sympathizing with the head. Wood's views, as well as all others ever expressed, must be erroneous, if my doctrine is true.

Although sick headache is as common as it is dreadful, Bartholow and other writers on the Practice of Medicine have not said a word about it.

I will not attempt, in this communication, to explain the structure of the eye, to define hypermetropia and astigmatism, or to give the relationship existing between the eye and the stomach, so intimate that when the one is affected the other will sympathize, as in sick headache. Nor have I attempted to give a clinical history of the malady. In the REPORTER of May 6, 1882, you can read an admirably written clinical history by Dr. Smith, whose communication I read with interest. You will see from his communication, however, that we do not agree as to cause and treatment. If he will now send his male patient, aged 40 years, a history of whose case he gives in his communication, to an oculist, I promise him that the cause of the disease will be ascertained to be hypermetropia, either alone or combined with astigmatism, for which the positive cure will be glasses. Many others of his patients of whom he makes mention, if not all, doubtless have the same predisposing cause, and can be cured as easily.

I present the views embodied in this communication to the medical profession, asking that they be not condemned until proven erroneous. I have no doubt but that they will stand the test of investigation, and will ultimately be received as the true views relating to the cause and cure of sick headache.

I know that my theory, even if true, is liable to be brought into local disrepute by the correction of the defect of the eye being attempted by unskilled hands.

As a fitting close to this communication I would ask medical practitioners everywhere, if prepared to do so, to put every case of sick headache to the test, or if not prepared themselves for this kind of work, advise their patients to go to an oculist, that my theory may thereby be put to the test also. If my theory is erroneous, I want it to fall; if true, then millions who are now suffering may be permanently cured.

Many patients may appear to have perfect vision for distance, when it is only made so by continuous tension of the ciliary muscle. This tension can be overcome, and the muscle put at rest, by the use of atropia, when the true condition of refraction will be shown. The whole of the hypermetropia, whether latent or manifest, should be corrected, likewise whatever astigmatism may exist.

If this communication incites any one to investigate, that he may determine whether my theory is correct or erroneous, I would be glad to learn, through this journal or otherwise, the result of such investigation.

My theory is now before you. May it stand if true, may it fall if erroneous.

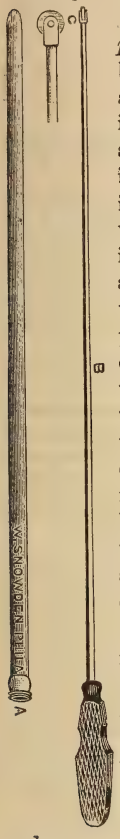
AN INSTRUMENT FOR THE REDUCTION OF FLEXIONS OF THE WOMB.

BY H. L. GETZ, M.D.,
Of Marshalltown, Ia.

About five years ago I devised, and have since used successfully, in a number of cases, the very simple and efficient instrument which will hereafter be described.

The objections to most, if not all, instruments used for the purpose above referred to are: First, when the flexion is severe it is impossible to introduce any of the instruments in general use without injury to the organ. Second, when introduced, if it is or can be done at all the point of the instrument encroaches severely upon the lining membrane of the womb, when an attempt is made to raise it into its natural position. Third, the instruments in use have not only the principal bearing at their point, but likewise upon a small point or surface; the same amount of force requiring to be applied for the reduction of the organ when the bearing is upon a small surface, as is required when it is made upon a larger one, the injury done to the part is apt to be correspondingly great as the bearing

surface is small. These defects are mainly overcome by this simple device:—



Plan of Instrument and its Application. — A common, flexible bougie (A), one quarter inch in diameter; A stylet (B), one-eighth inch in thickness, with plain handle; at opposite end, or rather about an inch and a half from end, the wire is somewhat reduced in thickness, and while firm enough to hold its shape, is tempered so as to have considerable spring, so that when straight, with a certain amount of force applied, it follows and springs around considerable of a curve. To facilitate the introduction and overcome the resistance necessarily encountered by the blunt point of wire coming in contact with the inner surface of the bougie, as the former is being pushed into the latter, a revolving disc (C), about one-eighth of an inch in diameter, is set in the end.

The best plan of application is to introduce the largest size flexible catheter or bougie which the canal will admit; with a very little skill these flexible catheters or bougies can be easily introduced into the womb, whatever may be the degree of flexion; now let it remain for a few minutes, and remove; introduce a next size larger, and so on, until you have reached say one-quarter inch in diameter; now you are ready to begin the replacement; the delicate mucous membrane is now protected by the bougie; now introduce within the bougie your stylet, being careful to guard it (should the flexion be acute and considerable force necessary to raise the womb), to prevent its breaking through the bougie and injuring the womb; after having reduced the flexion, the catheter with the stylet within it may be removed. The after treatment may be such as will keep the womb in position. I am in the habit of using a hard-rubber intra-uterine pessary, cutting off the top so that the point will not bear against the mucous surface within the upper part of the womb, and also that any secretions may escape through the opening in top of pessary as well as at its side. I think most trouble which is experienced by the use of intra-uterine pessaries arises from their being too long; the inverted cup, or whatever it may be, is held by the vagina closely against the external os, and the point of the instrument pressed firmly against the inside, at top of womb, soon to irritate and do harm. Mr. Wm. Snowden, of No. 7 South Eleventh street, Philadelphia, has permission to manufacture, and will be pleased to fill orders for any who will try this simple device and test its merits.

REMOVAL OF A TUBERCULOUS TESTICLE.

BY H. G. WELCH, M.D.,
Of Defiance, Ohio.

Patient, Jno. M., age 30. About seven or eight years ago the patient noticed that his right testicle was enlarged, but gave him no pain. It enlarged gradually, and he could feel lumps (to use his own expression) in the body of the gland. For quite a while previous to the suppuration he could feel a lump about the size of a large hickory nut in the testicle. The natural sensation of the gland was diminished, though not entirely lost. It only gave him pain by rather rough manipulation and by its dragging on the cord. To relieve the latter he wore a suspensory bag most of the time for several years. I believe this was the only thing done for the relief of the trouble, except his own treatment of the sore with salves, after it broke down and began to discharge pus.

Patient had scrofula in his youth and at times after he had reached adult life. His grandfather on his father's side died of pulmonary consumption, and also a sister died with the same trouble a little over a year ago. He seemed to have a strong constitution and enjoyed good health most of the time.

Four or five weeks before the operation the tumor broke down and began the discharge of a thin, watery pus, exposing a semi-solid, cheesy mass, which formed a partial or small hernia.

October 26th, 1881. Assisted by Dr. Harris, I performed the operation in the following manner:—

An incision from within one-half inch of and on a level with the penis, was made along the median line to the bottom of the scrotum. Another on the right side of the testis was made, including a portion of the scrotum, elliptical in shape (after contraction), one inch in width by two in length. The testicle was then exposed, but was so adherent that it had to be dissected out. The arteries of the scrotum were secured and tied or twisted as fast as cut. When the testicle was dissected loose two strong silk ligatures were placed around the cord, about three-

fourths of an inch from it, and tightly tied, and the cord then cut off half an inch below the ligature. No hemorrhage followed. The edges of the scrotum were then brought together by three sutures. The ligatures applied to the cord were left long, and protruded through the opening left at the bottom of the scrotum, and acted as drainage. The patient was then placed in bed, one-third grain of morphia given, and the wound dressed with carbolized water, which was the principal dressing during treatment. Had some trouble first night to pass his urine; after first night no trouble in that line. Slept well nearly every night. Had frequent desire for coition. (And I have my doubts whether he kept from it more than the first four or five days, although strictly enjoined to the contrary). On the night of the 30th, four days after operation, there was a profuse hemorrhage from a small artery, which escaped and ceased to bleed during operation. It caused some alarm, both to patient and myself, as I was hastily called and supposed it to be the arteries of the cord. It ceased, however, without interference, and subsequently bled a little, two or three times.

Mr. Erichsen advises that the cord be enclosed, in all cases, in mass, with a strong whipcord ligature, and left to slough off. Bryant also recommends the same procedure, and says, "when tightly tied there will be no pain from cord."

Frank H. Hamilton prefers to transfix the cord with a needle armed with a strong ligature, by which the cord may be held while the vessels are secured and made safe, and then may be left in place for four or five days, as a safety guard, by which, in case of secondary hemorrhage, the cord may be pulled down and the arteries again tied. He further says that in the only case in which he tied the cord in mass the patient suffered great and unnecessary pain.

In this case Mr. Erichsen's plan was followed, and found to be efficient, and gave the patient no pain, whatever. The cord sloughed off and came away on the fourteenth day. The patient was discharged on the seventeenth day, nearly well. Forty days after the operation the patient was shot through the heart and instantly killed. At the autopsy the wound was found firmly and nicely healed.

—Horace Greeley once emphasized the value of a vegetable diet by the remark that after Nebuchadnezzar had been turned out to grass it was never recorded of him that he suffered from indigestion.

Hospital Reports.

THE AMERICAN HOSPITAL FOR SKIN DISEASES, PHILADELPHIA.

CLINIC OF JOHN V. SHOEMAKER, A.M., M.D.

Reported by Edwin Rosenthal, M.D., Ph. G., Assistant Physician.

A Case of Pustular Syphiloderma Simulating Smallpox—With its Treatment.

Gentlemen:—To-day I bring to your notice a case which, for its clinical significance, I deem of great importance, inasmuch as it has caused quite a number of physicians to fall into a serious error, which I am happy to say has not ended so unfortunately as it might have done. The following is the exact history which I gleaned from the patient I now exhibit to you:—

His name is John W., a native of Scotland, and he is 20 years of age. His occupation is that of a waiter upon one of the ocean steamships plying between this port and Savannah, Ga. Two weeks ago he noticed an eruption appear on the chest, causing him but little uneasiness; this spread very rapidly, and he sought the advice of a physician in Savannah, Ga., who said his blood was out of order, probably from his mode of living; he prescribed some pills, and requested him to abstain as much as possible from the delicacies of the table. These pills had no effect upon the eruption; in fact, he says, they increased the breaking out until it had spread all over his body. His appearance in the cabin of the ship was such that he was excluded therefrom and placed by himself in another portion of the ship. The captain and the crew looked with some suspicion on his disease, and as far as practicable isolated him; and upon arriving in port (this city) sent him immediately to the Custom House, from which place he was directed to one of the large hospitals; (previous to his going to the hospital he was brought to a physician who diagnosed the case as smallpox and directed him to the smallpox hospital); the assistants there said he had smallpox and directed him to the office of the Board of Health. At the office of the Board of Health he was examined, and as there seemed to be some misunderstanding in regard to the diagnosis, the health officer sent him to me, with the request that we should examine him, and decide upon his disease, and if not contagious, take charge of him until he is cured.

On questioning him I elicited the facts as above stated, with the following additions: He had had intercourse about eight weeks ago, in Savannah, Ga.; he had never noticed any sore upon his penis; and is perfectly unable to say how he acquired the disease.

We will now have him undressed, and I shall examine him before you. You see he is covered all over with a pustular eruption, very much resembling the appearance of smallpox—particularly on the face and arms. Opposed to this eruption being smallpox, we have, first, the history: occurring on the trunk, and then spreading to other parts of the body, while in smallpox it first appears on lips, palate and forehead. Secondly, we have no constitutional disturbance—the pain in

the back, calf of the legs, etc.; and then the appearance of the eruption: the pustules here are small and pointed, while in smallpox the condition is very different; the eruption, appearing first papular, after about a day becomes vesicular, then pustular, and on the eighth day of the eruption the pustules mature and become umbilicated; none of these changes have we here; and on the skin at the gluteal region you can see distinctly the coppery hue of the fading pustule. In the groin I can also feel the lymphatic glands enlarged, and in drawing back the foreskin I show you the scar of the chancre. This is, therefore, beyond all doubt, a very bad case of pustular syphilis. The patient, nevertheless, reiterates his statement that he had no knowledge of its presence. On the left arm you see a tattooed picture, and at first thought—not having examined the penis—I imagined this could have caused the disease. I have seen cases before result from tattooing the skin, and some years ago there were exhibited at the Philadelphia Hospital a number of patients suffering from different syphilitic affections resulting from being tattooed by the same man, who, on being caught and examined, showed every symptom of syphilitic impregnation, with mucous patches in the mouth, from which he had transmitted the syphilitic virus by holding the needles in his mouth when he went through the manipulations of tattooing the patients. Now, having arrived at the truthfulness and certainty of our diagnosis, I will call your attention to the method I shall pursue in the treatment of our patient.

Some years ago my attention was called to the "hypodermic injection of corrosive sublimate" in syphilitic disease, by Dr. Julius Kæmmerer of this city, who not only practiced the same with satisfactory results, but instructed his pupils, Doctors L. Wolff and Edwin Rosenthal, in its use. I have used this method of treatment in over one hundred and thirteen cases, within the last three years and a half, and can speak with some certainty of its results. I propose to use this treatment here, and shall use nothing else whatever, and you will, therefore, be able to watch from time to time the process of the cure, with me. I will now show you the method of making the injection, but before doing so, I will give you a few precautions, which I strongly advise you to follow. In the first place, see that your syringe is kept clean, and always use a glass one. Experience has taught me that they are superior to the metal or rubber syringes, for the following reasons: The metal syringe corrodes after using a few times, and becomes utterly unfit for use; and the rubber syringes are of too light material, they will very easily break. In the second place, look to your needles. See that they are well cleaned, free from rust, and of sufficient length. If they are dirty or rusty, they will act as an irritant, set up inflammation and cause abscesses. And if they are insufficient in length, they will not enter deeply enough, and instead of depositing the solution in the cellular tissue, where the absorbents can quickly act upon it, they will deposit it into a stratum of the skin where there are no absorbents, and thus again act as an irritant, set up inflammation, and cause abscesses. Again, in using needles, try to get one of gold, which, in my experiments, I have found the best, though those of steel will answer the purpose, if they be kept well cleaned and pointed. Also advise your patients to procure a syringe of their own, or if this be found impracticable get a needle for each; you will thereby lessen any chance for contagion. And also, when you are through with your needle, after an injection, see that it be well cleaned and oiled and run through it a bristle, well oiled. I have found that when you use a bristle, you keep the needle not only cleaner, but you lessen the chances of its rusting soon. A metallic wire run through the needle is one of the most certain causes of its early rust. If you follow out these precautions, you will be saved many annoying failures, and success will crown your efforts.

Now, in injecting the sublimate solution, I use a solution of the strength of one part of corrosive sublimate to one hundred parts of distilled water. In this proportion I find that I can more easily divide the dose I wish to give, as most of the hypodermic syringes are divided into tenths, and therefore a syringeful would very soon tell you how much corrosive sublimate you are using in the injection.

I generally make the injection either in the infra-scapular or sacral regions, because I have found these parts the least susceptible, and again they contain more cellular tissue than any other part of the body. Sometimes the injection is followed by a burning pain, which may be from the slightest annoyance to the most intense, varying with the susceptibility of the patient; it is often aggravated by the patient lying upon the spot of puncture. For the relief of this pain I tell the patient to rest quietly, and if it is not then relieved, I apply a lump of ice to the part; some use morphia in combination with the corrosive sublimate in the injection, for the relief of this pain. I have had unusual good results in my injections, as it was very rarely that intense pain followed the puncture.

Now, gentlemen, you will notice how I make the hypodermic injection; I seize a fold of the tissue in the infra-scapular region with the thumb and forefinger of my left hand, and push the needle of the syringe, held in my right hand, deep down into the cellular tissue, and I slowly press out the contents of the syringe; I then remove the syringe by a rotary motion, pressing back the tissue with my finger of the left hand and with the other fingers slowly distribute the solution into the surrounding tissue, by gently pressing and kneading about the point of injection. Before making the injection I see that all the air is forced out of the syringe, and I always oil the needle with pure olive oil before I push it through the tissues.

This will be the only treatment pursued here, and at my next clinic I will bring this patient again before you, and you will be surprised to see the change that will take place in the appearance of the eruption. You will see the pustules dry and gradually disappear, and in a few weeks we will discharge our patient cured. I will order my assistant to give him one injection of one-tenth of a grain of corrosive sublimate daily, and that he should increase it, mimim by minim, every day or every other day, as our judgment may di-

rect, till we have him under the influence of the drug, and then we will slowly decrease the dose until our patient is cured.

In speaking of the hypodermic method of treating syphilitic affections, I must say that I believe it to be the only rational method of eradicating this disease.

Why? I have treated patients by internal medications over and over again, with the most unsatisfactory results. In one case that I now recall, I have given grain after grain of calomel, corrosive sublimate, and the other salts of mercury, for nine months, until I was thoroughly disgusted with it; and then using hypodermic injections, I was soon able to discharge my patient cured. This method I have used in the most obstinate cases, and have yet to see a total failure. It begins its good action in a week or ten days, and as soon as this has been obtained the treatment progresses very quickly to a cure.

I now wish to rid your mind of an error in which we commonly believe: Some authors say that mercury acts internally by forming an "albuminate." I do not see how this can be possible, as albumen is the antidote for corrosive sublimate, and if it should form an "albuminate of mercury," I cannot see what good it would do. In administering mercury internally it forms, I think, an "albuminous mixture" or solution, and the reason that we have such bad results from the use of this drug is this: The mercury may form an insoluble albuminous mixture, which will not remain long enough in the body to become absorbed, but passes out with the stools. This can never take place by the hypodermic method, for it becomes, shortly after depositing it in the tissues, absorbed, and begins at once its good action.

Syphilitic Periostitis.

The next case I show you is William O., age 35 years. He is suffering from syphilitic periostitis of the metacarpal and phalangeal bones of the left hand. In him I wish to demonstrate to you the process of cure as it is taking place, by the use of hypodermic injections. In the first case I showed you the beginning of the treatment; in this case I show you the process of cure which is near the end. Now, it will be of great interest to you to know the history of this case, with the history of the treatment; and I brought him before you for this purpose, and also to show you the extent of the disease. The difficulty in the hand began last July; previous to this he had evidences of syphilitic sores on all parts of the body, and presented evidences of scars where the syphilitic sores were. After being under the treatment of several physicians he applied at the Hospital for relief. At this time I found the hand and fingers enormously swollen, covered with tubercles, some in the process of formation and others in the process of ulceration, and, upon examination, I found gummy deposits were formed along the course of the metacarpal and phalangeal bones. He had received treatment of all sorts and varieties, and when he came to me, with the parts so enormously swollen, I immediately plunged a bistoury into the inflamed and swollen mass, down to the bone, to relieve tension, deplete the parts, and give vent to the accumulated pus. The operation gave him immediate but only temporary relief, and he soon returned to me, and I, from time to time, made use of the bistoury, without any decided and permanent benefit, until at last I began the use of the hypodermic injections, with the result you see here: The inflammation has subsided, the infiltration has become absorbed, and here you see him come back almost cured.

In conclusion, I would advise you to use this method of treatment in your practice, for the following reasons:—

First. For the quickness of its action, as you will see by the first case I showed you; for what treatment can act as quickly as this method.

Second. For the accuracy and precision of its dose, and—

Third. Which is important to the physician, the simplicity and "easiness" of its application. Here one may in a very few moments measure out and give the desired dose, and the method is so simple that it could easily be learned by the most ignorant; besides, any uncomplicated system of medication is sure to be acceptable to the physician of average intelligence.

I again recall your attention to the precautions I have advised, and tell you that much of your success will depend upon them. Much of the ill success recorded by European and other observers depends upon a neglect of the commonest rules to be followed in any hypodermic injection. Some of them use the solution in a too concentrated form; others, again, use it in a too dilute form, hence they must inject twice and thrice the quantity at one time, to get the result, and thus set up inflammation and its results. Others, again, do not give the remedy time to act; while the majority of physicians do not care to take the trouble of giving a hypodermic injection every day.

Here, then, gentlemen, I have demonstrated to you one of the best methods, I think, there is for the treatment of all syphilitic affections, and in concluding, lay particular stress on one subject I very near forgot mentioning to you: Do not forget the susceptibility of some individuals to the use of mercurials; if you should meet such a patient, the only precaution you need is to begin with the smallest doses and slowly increase.

Aloetic Pills.

M. Audhoui, in *Le Médecin Praticien*, considering that the preparations containing aloes in general use are of too irritating a nature, recommends the following pill mass, which he constantly uses:—

℞.	Aloes pulv.,	ʒ ss
	Potass. bitart. pulv.,	ʒ ss
	Sapo. amygdal.,	ʒ j
	Acaciæ gum pulv.,	ʒ ss
	Syr. simplic.,	q.s.

Mix carefully the powders and soap, add the sugar and divide into 100 pills.

M. Audhoui prescribes one, two or more of these pills, according to the condition of the digestive organs, after meals.

Editorial Department.

Periscope.

Multiple Sarcomata.

In the *Medical Times and Gazette*, Dr. A. R. Anderson records the following unusual case:—

J. B., aged forty-three, was admitted into the hospital on May 3d, 1880. He said that up to four months previously he had been in good health, and at that time he wrenched his shoulder at work, and soon after noticed a swelling on it, which was shortly followed by like swellings on the chest and head, the rapid increase of which, both in number and size, caused him to apply for admission into the hospital.

On examination, he was found to have eight tumors—three of which were situated on the front of the chest and five on the head. Those on the chest were placed one on either clavicle, the third over the upper part of the sternum. The one on the right clavicle was the first to appear; it lay over the inner third of the bone, and had existed for four months. It increased rapidly in size, and had at this time attained the dimensions of an orange, measuring three inches and a half along its greatest semi-circumference, and two inches and a quarter along its shortest. It was rounded, hard, painless when touched, and firmly connected with the subjacent bone. Over the sternal end of the left clavicle was a much smaller swelling, having the same characters, and measuring one inch by one inch. The third, on the sternum, was irregular in shape and flattened; it measured two inches by one inch.

Of those on the head, the largest was seated in the centre of the forehead, and was rounded, and quite soft and semi-fluctuating, especially in the centre, differing markedly in this respect from those on the thorax. Close to the lateral boundary of the forehead another tumor existed on either side. These were not more than a quarter the size of the previous one, but possessed the same general characters. The fourth was over the left parietal bone, and was quite small. The fifth and last of these growths lay near the apex of the lambdoidal suture, and had a somewhat remarkable history. Five weeks before his admission, it was stated to have been the size of a pigeon's egg; since then it had diminished much in size, again increased, and again disappeared. Its site was, at the time of his admission, only marked by a soft, boggy patch, about one inch and a quarter in diameter and very slightly elevated above the surrounding integument. The edges of the patch were firmer, and gave the sensation of a ring. The subjacent bone felt firm and hard.

With regard to his general condition, he was fairly well developed, and had been muscular, but had lost flesh latterly. He ate and slept well, being free from pain. There was nothing in the family history bearing on the nature of his complaint. Was ordered to take a mixture containing ten-grain doses of iodide and bromide of potassium three times a day.

On June 1st, while helping another patient into bed, and without making any undue muscular effort, his right humerus broke, with a loud snap. A transverse fracture was found in the lower third of the bone, and the limb was put up on an angular splint. There had been no improvement up to this date in his condition; indeed, the growths had increased in size, and another had appeared over the left mastoid process. There was, however, no sign of any tumor at the seat of fracture.

June 19th. Fracture of the left humerus was caused to-day in the lower third of the bone, by the very slight muscular effort employed in raising the corresponding hand to his head. He had been warned to be cautious in his movements, and had lifted his arm slowly and deliberately. There was no appearance of a new growth in this situation; but the left eye had become prominent and vision much impaired, clearly indicating one within the orbit.

He was now in a sad state of helplessness, and decided shortly to go home. He was discharged on June 26th, and subsequently attended by Mr. Joseph Thompson, through whose courtesy I was enabled to watch the case to its termination.

After leaving the hospital the swellings increased enormously in size, and fresh ones appeared; at the same time he grew rapidly weaker, and shortly before death his condition was as follows:—

On the *head*, the tumor in the centre of the forehead was as large as a saucer, flattened on its surface, and raised four inches from the surrounding skin; the integument over it was thickened, almost horny, and pigmented, being of a dark brown color; large veins were to be seen traversing it. The forehead tumors on either side of this one were somewhat larger than when he went home, but had not increased in size so rapidly. Behind the left ear was a swelling as large as a hen's egg, and another of the same dimensions existed now over the posterior fontanelle; a third, rather smaller than these, was situated just above and behind the right ear. The left eyeball was protruded on to the cheek, and vision entirely lost. A red, sprouting, granulating mass projected here.

The tumors on the head had these characters: They were not so distinctly circumscribed as those on the body; they were softer to the touch, semi-fluctuating in some parts, and had surfaces which were fairly smooth or only slightly tuberous; they were firmly fixed on subjacent parts, and could be handled without pain; neither the skin covering them, nor the neighboring lymphatic glands, were involved.

On the front of the *chest*, five of these growths were situated. The largest lay partly in front of and partly below the right clavicle, and was the size of a cocoanut; a second was situated over the inner third of the left clavicle, a third over the centre of the upper part of the sternum, a fourth also in the middle line below this. All these were about half the size of the first-men-

tioned, and the fifth was larger; it occupied a spot immediately below the left nipple. They were all firm and hard, with distinctly circumscribed outlines and nodular surfaces, painless when touched, and firmly fixed. There were no glandular enlargements or skin implication. On the right acromion was a single tumor, and a corresponding one lay on the left, with a third just below it, connected with the humerus—all the size of eggs, hard, nodular and immovable. There was not the least attempt at union in the fracture, either of the right humerus or of the left, and in this situation there existed now, on each side, a swelling as large as an orange, firm, fixed, and evidently growing from the interior of the bone; and lastly, in the middle of the extensor surface of each forearm was another tumor, having the same characters as the above and being of almost the same dimensions.

He was in a state of extreme emaciation, and on the sacrum was a bed-sore. He complained much of weariness and general soreness, he said, from lying, and required to be constantly moved. Pains in both knees were causing him much trouble, but there were no signs of any tumors there. Percussion over the thorax and abdomen did not detect any abnormal dullness, and there was no enlargement of the abdominal viscera. He gradually sank, and died on the morning of Christmas day, 1880. His intellectual faculties remained clear to the end.

Rheumatic Diathesis and the Initial Lesion of Syphilis.

Dr. C. B. Lockwood thus writes, in the *British Medical Journal*:—

Most observers are agreed that the course of syphilis may be greatly modified by the diathesis of the patient. Reference to the writings of authorities on syphilis, and to their discussion at the International Medical Congress, shows that their observations are extended chiefly to the later stages. I am not aware that any one has recorded observations showing that the rheumatic diathesis can modify the initial lesion. Primary syphilitic sores come under notice, which at first present ordinary characters. They afterwards become "inflamed and phagedænic" (Hill and Cooper, *Manual of Venereal Diseases*, London, 1881, p. 466), and may cause considerable destruction of tissue. Many attempts have been made to explain this occurrence (*Ibid.*, p. 468); debility, patients' habits, position of the sore, and peculiarities of the virus, have all been adduced. In the cases mentioned below, all of these can be eliminated, except the last. If the infecting virus in such cases as these be peculiar it must expend its peculiarities upon the sore, for the other manifestations are not unusual. Moreover, these sores do not cause similar ones when inoculated. It therefore remains to explain what Messrs. Hill and Cooper state, and what personal observation has frequently confirmed, why "patients are met with who, but for the rapidly necrosing chancre itself, present every sign of good health" (*Ibid.*, p. 469). The following cases may suggest a cause. They are not numerous, but seem to be more than coincidences:—

A patient, aged 26, came under my care in September, 1879. He had what appeared to be an excoriation near the frænum. Ordinary applications had no effect upon it. By the end of September the sore was larger and considerably indurated; not inflamed or particularly ulcerated. The inguinal glands were indurated. About the beginning of October the character of the sore changed. It became inflamed, very painful, and excavated. There was a profuse, thin, and slightly sanguineous discharge. Small sloughs occasionally separated, and the ulceration extended until about a quarter of the glans penis was destroyed. The appearance of the disease at this time was quite characteristic. The sore was acutely inflamed and phagedænic. In November there was acute inflammation of the dorsal lymphatics of the penis, with roseola over the chest and belly. The treatment adopted locally, during the whole course of the disease, was the use of warm baths and the application of iodoform. Constitutionally, two and a half grains of blue pill were administered night and morning. The effect of mercury was to cause the sore to spread, and increase the pain. Iodide of potassium with tartrate of iron was given, in increasing doses. Opium was administered, to relieve the pain. Improvement was rapid and continuous, and the sore healed. Afterwards, the patient had a slight tubercular syphilide and ulcerated throat. These were relieved by increased doses of iodide of potassium (30 grains) three times a day, and calomel vapor baths (15 grains) every other night. About February, 1880, he discontinued the iodide of potassium, and took half a grain of green iodide of mercury each night, for a few months. He is at present free from symptoms.

There did not appear to be anything to account for the course of this patient's disease. He had not taken mercury before the inflammation began. He appeared strong and healthy. His circumstances were comfortable, and his life regular. The following case seemed to throw some light upon it. About December, 1880, W. H., aged 25, a bookbinder, came under observation in St. Bartholomew's Hospital. He had an inflamed and phagedænic chancre, which resembled, in all its characters, that of the first patient. He also had lymphatic engorgement and roseola. His throat was ulcerated. Mercury increased the ulceration, which had destroyed about a quarter of the glans penis. Iodoform was therefore applied to the sore, and iodide of potassium and tartrate of iron were administered internally. By the end of January, 1881, the sore was healed, the patient left the hospital, and has not been seen since. There was nothing about this patient which would account for the inflammation and phagedæna. He, like the other, appeared strong and healthy. However, I remember that the first patient was very rheumatic. He had suffered from rheumatic fever twice, and from one or two slighter attacks. He had had endocarditis and iritis. Upon inquiry it was found that W. H. had been laid up in the London Hospital seven years before, suffering from rheumatic fever. He said his heart had been affected, but no murmur could be detected. There was no family history of rheumatism.

Two other cases, in which hard sores became inflamed and phagedænic, have come under notice. In one there was a clear history of previous rheumatism. The other had never had rheumatism; but his father had had rheumatic fever, and his mother suffered from chronic rheumatism. This case is progressing favorably, iodoform being applied to the sore, and $\frac{1}{32}$ grain of bichloride of mercury given three times a day. It may be mentioned that he had inflammation of the dorsal lymphatics of the penis. This occurring in two cases denotes the intensity of the inflammation. Mr. Hutchinson, in the *Medical Times and Gazette* (quoted by Hill and Cooper, page 469), has attempted to account for the origin of phagedæna. "He considers the patient's temperament. Certain persons have special proclivities to acute inflammation; and such a patient, if attacked by a chancre, would be more likely to have a phagedænic form of chancre." Bearing this in mind, and remembering how prone rheumatic patients are to inflammations, it might be anticipated that in them chancres would become inflamed. Four cases form insufficient materials from which to draw sound conclusions. But these are suggestive, and serve to bear out theoretical considerations.

As regards the treatment of these cases, in two mercury certainly did harm. The third was not under observation a sufficient time to form any conclusion. The last is improving under very small doses of a mild preparation. He had never had rheumatism himself, and his predisposition was probably least. Experience teaches not only that phagedæna is seldom benefited by mercury, but also that iodide of potassium is good for rheumatism. It can, therefore, be understood why these cases were so amenable to treatment by the latter. Therefore, in cases of syphilis in which the initial lesion is inflamed and phagedænic, and in which there is a history of rheumatism, it is probable that iodides will be of service at an earlier stage than usual. Mercury should be administered with the greatest caution, if at all.

Hyperpyrexia in Acute Rheumatism.

A Committee of the Clinical Society to whom the question of hyperpyrexia in acute rheumatism had been referred made their report to the Society, May 26th. From the *Medical Times and Gazette* we glean the following conclusions that were arrived at:—

1. That cases of hyperpyrexia in acute rheumatism appear to prevail at certain periods, having in the last decade been remarkably numerous in the years 1873-76, whereas latterly they appear to have been much less frequent. That such excess corresponds in a certain degree, but not in actual proportion, to a similar excessive prevalence in acute rheumatism generally. That the largest number of cases of hyperpyrexia arose in the spring and summer months, whereas rheumatism is relatively more common in the autumn and winter.

2. That while very little difference obtains between the two sexes in regard to proclivity to rheumatism, the proportion of males to females exhibiting hyperpyrexial manifestations is 1.8 to 1, but that as to age no such marked difference exists; nor as to occupation.

3. That the subjects of hyperpyrexia show no undue rheumatic tendency as regards family predisposition.

4. That cases of hyperpyrexia preponderate in first attacks of rheumatic fever.

5. That hyperpyrexia is not necessarily accompanied by any visceral complications, but may itself be fatal. The complications with which it is most frequently associated are pericarditis and pneumonia.

6. That the mortality of these cases is very considerable, hyperpyrexia being one of the chief causes of death in acute rheumatism.

7. That although present in a certain number of cases, and then of much value, from their prodromal significance, neither the fact of the abrupt disappearance of articular affection, nor the similarly abrupt cessation of sweating, is an invariable antecedent of the hyperpyrexial outburst.

8. That the supervention of delirium or other symptom of nervous disturbance is very frequent, either antecedent to or simultaneous with the hyperpyrexia.

9. That there is considerable variability in the date of the occurrence and in the duration of the hyperpyrexial condition, ranging, according to our observations, at least, from the fourth to the thirtieth day.

10. That when death results it has occurred mostly in the second and third weeks of the rheumatic attack.

11. That the post-mortem examinations in a certain proportion elicited no distinct visceral lesions, and that, when present, the lesions are not necessarily extensive.

12. That the prompt and early application of cold to the surface is a most valuable mode of treatment of hyperpyrexia. That the chances of its efficacy are greater the earlier it is had recourse to. That the temperature cannot safely be allowed to rise above 105°. That failing, the most certain measure—viz., the cold bath—cold, may be applied in various other ways; by the application of ice, by cold affusions, ice-bags, wet sheets, and iced injections.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. W. O. Roberts, of Louisville, in a report read before the Kentucky State Medical Society, gives a useful review of the progress of surgery in 1881.

——That fortunately rare disease, Cancer of the Lung, is the subject of a reprint by Dr. G. W. H. Kemper, of Muncie, Indiana. It is almost needless to say he regards such cases as absolutely hopeless. The only palliation is opium.

——Now that the manœuvre of lithotrity is generally approved of, the observations upon it by

Dr. Reliquet deserve close reading. The little pamphlet published by A. Delahaye, Place de l'Ecole de Médecine, Paris, is entitled "La Lithotrite doit être faite sans Traumatisme," and the title expresses the whole of the author's aim. The argument is well put and forcible.

——An able summary about asylums and their reports is given in a reprint by Dr. C. L. Dana, of New York City. He estimates that the number of insane in the United States in 1880 was about 90,000; of these, in asylums about 40,000. There are more insane in New England than elsewhere, but the rate is decreasing there. The annual cost per patient is from $200 to $250. He closes with some just criticisms on the reports, which we quote:—

What, as a medical man, one would criticise most, is the absence of the scientific spirit in the gentlemen who are the authors. To run an asylum on an economic basis is something, but it is not all. There is a science known as psychiatry. We have in this country three hundred gentlemen who have almost exclusive opportunities of studying it upon their forty thousand patients. But they, as a rule, contribute nothing of real scientific value to our literature. Such a thing as this is unparalleled in any other civilized country, or in any other medical specialty.

——A reprint by Dr. C. T. Bull, of New York, treats of syphilitic diseases of the lachrymal apparatus. He divides them into lesions of the lachrymal gland, of the caruncles and of the passages. When the inflammatory action is severe, he uses mercurial treatment, and remarks:—

"A very excellent method of administering mercury in these cases is to use two drachms of mercurial ointment, by inunction, upon the inner aspect of the arm or side of the chest, and at the same time give the mild chloride internally, in doses of grain one-sixth to one-fourth every hour or two, carefully watching for the first symptoms of the action of the drug. In many cases a beneficial effect upon the lesion will be observed on the third or fourth day, and then the mercury may be either entirely discontinued, or given in smaller doses at longer intervals. In many of these cases complete recovery follows such a course of treatment; all signs of inflammation and obstruction in the duct disappear, and the patency of the duct is restored without any incision or probing.

BOOK NOTICES.

Transactions of the American Gynecologial Society. Vol. VI. For the year 1881. Philadelphia: H. C. Lea's Son & Co. 1882.

This handsome volume appears with all the æsthetic elements of toned paper, antique type and gilt edge, which characterized its predecessors. Gynecologists have so much to do with the fair sex that they have contracted its love of finery, we suppose. Many solid articles will be found in its 542 pages, and the indexes of the literature relating to gynecology and obstetrics, added at the close, are especially useful. The writers are numerous, and as we cannot pretend to do justice to all, we shall mention only a few, not meaning that they are, for that reason, the most important.

Dr. Jenks' article on the practice of gynecology in ancient times is the sort of contributions we like to see, as there is entirely too little attention paid in this country to medical history. He condenses a great deal of interest in a few pages.

Dr. Bozeman's article on "Genital Renovation" has in it much of value, but we must condemn the appearance of pedantry in his nomenclature. Is there any real advantage in writing language like this: "Genital renovation, or genital anakainosis, as opposed to genital kleisis, particularly by kolpostenotomy and kolpoecpetasis in urinary and fecal fistules, without interference with the functions, is the title, etc.?" With an English-Greek lexicon at hand, it is easy to fill a page with neologisms, but this mania, now so prevalent with certain specialists, does not advance science.

The subject of "Bursting Cysts of the Abdominal Cavity" is discussed with great clearness and with some very striking cases, by Dr. Goodell.

The proper treatment of that most obstinate complaint, lupus of the vulva, is clearly set forth by Dr. I. E. Taylor.

Several interesting obstetrical points were also touched on in the papers.

Practical Medical Anatomy. By Ambrose L. Ranney, A.M., M.D., etc. Wm. Wood & Co. 1882.

This is a new arrangement of anatomy, more on the plan of Hyrtl's work than any other we recall. It is aimed especially to serve the purpose of the practitioner, and connect anatomical with medical facts. The project is a good one, and Dr. Ranney has carried it out well.

We have noted occasionally loose statements, as that (p. 15), owing to an imperfect development of the frontal sinuses in the Australians, a want of resonance to the voice is produced! The authority for this dates from 1700 (!) and it is an absurd fiction, their class of languages being vocalic and resonant (Müller *Grundriss der Sprachwissenschaft, Bd.* II, § 1).

The illustrations and paper cannot be mentioned with praise. The volume is one of Wood's Library of Standard Medical Authors.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**

PHILADELPHIA, PA.

THE LAST SCENE OF A SAD HISTORY.

The imperfect reports of the examination of Guiteau's brain hurried into some of our contemporaries were sufficient, however, to indicate that no marked anomaly, either in symmetry or normal character of brain substance, was found. This is borne out by the more ample details now published.

Of course, this is far from conclusive that there was no mental aberration ; it may be said neither to tell for nor against that hypothesis ; but the confident assertion of some of the experts, that there was marked asymmetry of the head, that "any one could see that Guiteau was a lunatic," etc., receive a well-merited rebuke from this investigation.

It is to be regretted that, like so much in connection with this unfortunate case, here too an opportunity for a professional wrangle offered itself, and was at once seized upon. Not only this, but the public all over the land was made acquainted with matters relating to the quarrel which should have been regarded as belonging to the personal relations of those concerned.

Must this washing of professional dirty linen in public continue, without an effort to stop it? There is a legitimate difference of opinion on many—shall we say on most?—professional questions, and for the one side or the other to pour its grievances into the long and ready ear of the first newspaper reporter who presents himself, is very discreditable.

We extract the following from the official report, as of most interest in the case :—

Head.—The first thing noticed was a scar on the scalp, an inch long, situated longitudinally, just above and behind the left temple, but there was no corresponding mark upon the skull. The right parietal bone was slightly flattened in its upper and anterior part, covering about two inches square and terminated at the coronal suture. This flattening was confined to the outer plate, and was at the expense of the diploic structure, as there was no bulging of the inner table, immediately beneath, that could be discerned. It was regarded of such a trivial nature as to make it unnecessary to take accurate measurement by transverse sections of the skull at this point, or to remove the skull to the museum for more minute examination, and it was buried with the remains.

There were no other points of asymmetry noticeable. The cranial sutures were distinct. There was no visible trace of a frontal suture, the two halves of the frontal bone being thoroughly welded. On the inner surface of the skull the usual bony prominences were well marked, also the pacchionian depressions. No abnormalities were discovered. The thickness of the skull was not measured ; but, to the naked eye, it was normal. The diameters and cubic contents of the skull were not taken, nor the relative size of the fossæ.

Brain Membranes.—The dura mater was quite strongly adherent in places to the inner surface of the skull, viz., near the trunks of the middle meningeal arteries ; also near the longitudinal sinus in front, but could be stripped cleanly from the bone at all these points of attachment, as there was no roughening of the skull here or elsewhere. There was no exudation on any part of the inner surface of the dura mater. Quite a number of pacchionian granulations were distributed along the course of the longitudinal sinus. The cerebral sinuses contained but little if any blood. The dura mater, pia mater and brain were adherent to each other on both sides along a limited portion of the longitudinal fissure adjacent to the pacchionian granulations.

Arachnoid.—There were very well marked milky opacities of the arachnoid, but no apparent thickening, extending over the upper portion of the convex surface of the hemispheres only ; as elsewhere, the membrane was perfectly normal. These opacities were confined to the upper portion of the sulci in this vicinity exclusively, and were such as are often found without previous history of disease. The sub-arachnoid space contained very little fluid. Pia mater was easily

stripped from all parts of the brain. The blood vessels of the membranes and brain were empty, and the general appearance of the brain anæmic or bloodless. Sufficient examination was made of the large blood vessels of the brain to determine that they were in a healthy condition.

Brain.—The brain entire, with a portion of dura mater attached, weighed 49½ ounces, about the average weight for an adult male. The consistence of the brain was normal; its specific gravity and measurements of its chords and arcs could not be obtained, owing to lack of facilities. There was no apparent asymmetry of the two hemispheres. As regards contour and shape, exact studies were not made, and the comparative weights of the different parts were not obtained; cerebellum was well covered; the occipital lobes were not noticeably blunt or sharp.

There was an obvious want of precision in making the explorations, as is seen from the above. The blame for this, of course, each party wants to throw on the other. It is one of those disputes in which the unprejudiced observer will divide the onus about equally.

So ends a history which has been throughout, in its medical and surgical relation, with regard both to the murderer and his victim, one to which the profession of the United States cannot "point with pride." It has been a series of blunders, misstatements, and quarrels, beginning with a flagrant violation of professional courtesy, and concluding with an effort to dodge the blame of a slovenly-conducted post-mortem.

CONFIDENTIAL COMMUNICATIONS TO PHYSICIANS.

The following words of advice have been rendered necessary because of the freedom, the unwarrantable license, with which many physicians are wont to discuss the secrets of the consultation room. Many conscientious men who would not disclose the confessions of patients to those outside the pale of the profession, yet hesitate not to detail names and cases to their professional brethren, who in turn relate them to others, until in many cases they reach the ears of friends or relatives of the patient, and his character is justly or unjustly, as the case may be, but none the less surely, injured. Patients rarely ask secrecy from their physicians, either because they do not think of it, or else they take it for granted. Still, the physician is none the less bound to secrecy; and the conscientious medical man will so consider it. The secrets told in the consultation room of the physician should be as sacredly guarded in the innermost recesses of his most secluded nature, as are the revelations made to the Roman Catholic priest in the confessional. If we but stop and reflect for a minute, all of us in active practice can recall many instances where, by a breach of this implied trust, the character of a man or woman could be utterly and completely ruined for life, while the whole foundation of the domestic happiness and prosperity of many families could be razed to the ground by but a few ill-timed and uncalled for words from the physician. The story is related, on most undoubted authority, of a murder that occurred some years ago in Ireland. The victim was the brother of a parish priest, and no trace of the murderer could be found. A year or so afterward a man well known to the priest revealed to him, in confession, that he had murdered his brother. He received absolution for his crime and went his way in peace. For fifteen years this man lived in close proximity to the brother of his victim, whom he met every few days, and not a breath of suspicion did the priest utter against him, so sacred did he hold the revelations of the confessional. Finally, after this long period, one night the murderer was sent to summon the priest to the deathbed of one of his family who lived a mile or two from the village. While walking along the country road, they came to a lonely spot, when the priest's companion turning to him, said, "Father, this is the spot where I murdered your brother," and he then detailed the circumstances of the crime. The priest said nothing at the time, but the next morning had a warrant issued for the arrest of the murderer, who was tried, convicted and hung. For fifteen years this man had, through a sense of duty, stifled the instincts of nature, until, when the history of the crime was admitted to him outside of the confessional, he felt at liberty to bring the criminal to justice. Here, then, is an example for physicians to follow. They should treat their patients' confessions as confidentially as did this priest the story of his brother's mur-

derer, lest by neglecting to do so they may cause misery altogether at variance with the philanthropic nature of their profession.

POST-MORTEM EXAMINATIONS.

There is a widespread and eminently natural aversion among the average public against allowing post-mortem examinations upon the bodies of relatives and friends. The dead brother, sister, mother, father, wife or husband is considered far too sacred to be desecrated by the knife of the surgeon; hence permission to make a post-mortem examination is, in the majority of instances, refused. That this ought not to be so, we all, as physicians, fully realize. It is an admitted and universally accepted fact that something can be learned, that some benefit to science can be derived, from a critical examination of every dead body. A careful and accurate ante-mortem diagnosis may have been made, the accuracy of which is fully attested by the autopsy; yet some anomaly of anatomical arrangement, or some pathological condition, unsuspected during life, that might account for some symptom so trivial as almost to have escaped notice, will serve as a small point, the aggregation of many of which may do much toward furthering the science of pathological histology. The more post-mortems we have, the more rapid will be our advance in all that pertains to the intelligent and practical, as opposed to the empirical and theoretical, treatment of disease. We of to-day, as a class, are opposed to cremation, because it is not the prevailing fashion of disposing of the dead; yet our ancient Roman ancestors, when in the zenith of their intelligence and power, considered this the most proper way of terminating the existence of the body. So with post-mortem examinations. We are opposed to them, and consider them harsh and unnatural, because they are not fashionable. Physicians should endeavor to combat and overcome this prudish and anti-scientific sentimentality. They should take every opportunity, in ordinary conversation with patients and friends, to impress upon them the benefit to science and the advantage to mankind in general that would accrue from a more general allowance of post-mortems. By degrees, this course would tend to break down the social barrier that now exists, until the public would come to regard the autopsy as much a necessity following the death of a relative, as they now do the funeral. By this means, easily and gradually accomplished, we would be enabled to prosecute our pathological studies with ten times the rapidity that is now vouchsafed to us.

Notes and Comments.

An Important Contribution to the Physiology and Pathology of the Stomach.

Dr. Ludwig Eringer (*Deutsch Arch. f. Klin. Med.* Bd. 29, Heft 5 and 6) has contributed the following interesting observations to our knowledge of the physiology and pathology of the stomach:—

The author made a large number of experiments on himself and on many other persons, to decide at what time during the state of digestion free muriatic acid appears in the gastric juice. He found that the latter contained a plus of free muriatic acid during the second hour after a moderate meal, and during the third and fourth hours after an abundant and rich meal.

The examination of the gastric juice in a case of typhoid fever elicited the fact that the masses vomited during the period of the highest fever contained a large amount of free muriatic acid. As the results so far gained in this direction have been contradictory, this new addition to the chemistry of the digestion of persons suffering from high fever is rather important.

Examinations into the amyloid degeneration of the stomach showed, in eleven cases, that the vessels of the walls of the organ were also affected, more or less, by the same process of degeneration; frequently the muscularis, especially the muscularis mucosæ, often a part of the areolar tissue of the mucosa and the glandular structure, participated in the same morbid alteration.

The considerable dilatation of the stomach the author brings into causal connection with the coexisting considerable amyloid degeneration of the muscular walls of the organ. If the latter do not possess the tonus any more which is necessary to enable them to carry the weight of the contents of the stomach, a passive dilatation, its degree depending upon the amount of the contents, will temporarily ensue, and gradually

change into permanent dilatation, as the peristaltic movement becomes less and less sufficient for the locomotion of the contents of the organ.

Concerning the development of ulceration in cases of amyloid degeneration, the fact was noted, that it is not the amyloid parts which are attacked by this ulceration, but those parts which are not suffering from amyloid degeneration, but which, not being provided sufficiently with blood from the degenerated vessels, fall a victim to the destroying influence of the gastric juice, which only an ample supply of alkaline blood can prevent. The physiological function of the stomach in cases of amyloid degeneration of the vessels of the mucosa of the organ undergoes this change, as proved by the frequently repeated examination of the contents of the organ in five such cases; that the gastric juice, at the proper time, exhibits a want of free muriatic acid.

Regarding the symptoms during life by which the physician, under certain circumstances, may be able to recognize this participation of the stomach in the amyloid degeneration, Frerichs first drew our attention to the fact that in the beginning the appetite vanishes, and from time to time vomiting takes place, while the tongue is not coated. But Eringer contends that these symptoms are so little definite and subject to such diverse explanations, that they can hardly be considered as possessing any diagnostic value. According to E.'s experience, the amyloid degeneration of the vessels of the stomach by itself does not exert any influence at all on the appetite; so that we will have to await further observations. Vomiting with clean tongue, absence of tenderness in the epigastric region, and amyloid degeneration in other organs, are the symptoms mainly to be relied upon. In conclusion, we will only add, that the favorable action of acids, and especially of muriatic acid, in cases of typhoid fever, seems to receive an explanation by the facts above mentioned, and that the latter give us the hint not to administer acids, for the purpose of assisting digestion, immediately after a meal, as heretofore done, but about two hours after the same.

The Rapidity of Conduction in Patella-Reflex. (?)

A. Eulenburg has lately made some interesting observations concerning the so called patella-reflex. He employed the graphic method and observed results, which, in one direction at least, were quite decided and uniform. He found that, in healthy persons, with very, very rare exceptions, the length of time consumed after a strong tap on the ligamentum patella, till the quadriceps femoris responded by contraction (duration of latency), never exceeded $\frac{2}{62}$ of a second (=0.03226). Cases in whom this time is still shorter, and may be said to vary between $\frac{1}{62}$ and $\frac{2}{62}$ of a second were frequently noticed among strong and healthy adults. In cases where, from some morbid cause, this same reflex (?) excitability is increased, the duration of latency can fall even below $\frac{1}{62}$ of a second (to 0.016313). The (centripetal-centrifugal) paths, along which the impression and the motor-impulse have to travel, to cause this phenomenon, amount to about one meter in length, while the velocity of conduction in the nerves in the normal state is equal to about 33.9 meters in a second. If it be true, as cannot well be doubted after the careful researches of Eulenburg, that the duration of latency in healthy individuals varies between $\frac{1}{62}$ and $\frac{2}{62}$ of a second, and that the same is less, even, in pathological cases, then the theory of the reflex character of the phenomenon becomes a very doubtful one. Further, we have proof of the fact that the duration of latency diminishes in the same ratio as the phenomenon itself appears less pronounced; if the conduction in the centrifugal nerve-paths becomes so slow that it falls below a certain norm, the patella symptoms cannot be observed any more. This proves what Westphal contended from the very beginning, that these phenomena are not of a reflex character at all; they are in intimate connection with the so called muscular tonus and with the integrity of those peripheral paths which receive the irritation and carry it further. The latter theory would also better explain the absence of this phenomenon in locomotor ataxia; here the tactile sense is decidedly diminished, and the muscular tonus as decidedly decreased.

Successful Sponge Grafting.

In the *Medical Times and Gazette*, Dr. W. Winslow Hall reports a case of sponge grafting in a girl, age twenty, who was suffering from two large ulcers on the dorsum of the left foot. She was a pale, anæmic girl. The larger ulcer was three inches in diameter and one inch deep. The other one was smaller. She was given cod-liver oil, and charcoal poultices were applied to the sores, which were syringed twice each day, with carbolic lotion (one to forty). Under this treatment the ulcers took on a more healthy appearance. A thin slice of ordinary sponge was soaked in a very strong solution of carbolic acid for fifteen hours, and then carefully washed in a more dilute solution, till there remained but a faint smell of the acid. Bits of this sponge slice were now

packed into each ulcer until rather above the level of the adjacent skin, and a cotton band age was applied over all. After about three months and a half, the patient left the hospital. Her progress was slow but uninterrupted. New skin spread gradually under the margins of the sponges, and as these margins became loose they were clipped away. The former ulcers are covered in by healthy skin almost on a level with the surrounding skin surface.

In this case the preliminary treatment consisted merely in disinfecting the sponge with carbolic acid. And as the case wore on it became evident that the sponge-tissue was not becoming incorporated in the patient's foot. It rose by degrees in the wound, and fragments were clipped away from its surface. In time it became stationary, and then new skin spread under its edges, so that, in fact, the sponge was slowly shoved out by the new tissue replacing it. In the event of the occurrence of a similar case it would be interesting to compare the quantity of sponge placed in the ulcer with the sum total of the fragments clipped away during the progress of the case. The employment of sponge-grafting was undoubtedly of value in this case. Nature had been allowed to treat two similar ulcers on the same leg, and had left two large cicatrices firmly adherent to the underlying bone. These caused great deformity, and could hardly be called perfect results. The result of the use of sponge-grafting was that a pliable cicatrix was obtained almost on a level with the neighboring skin; the foot was saved from deformity, and its usefulness was not impaired.

Phthisis Among Needle Manufacturers.

The *British Medical Journal* says: In his recent report to the Stratford-on-Avon Combination of Sanitary Authorities, Mr. G. H. Fosbroke again comments upon the not uncommon prevalence of phthisis among needle manufacturers. During 1880, no fewer than 45 deaths happened from this disease, 24 being registered in Alcester, which had then a population not exceeding 20,000; the remaining 21 deaths occurring in the Evesham and Stratford Districts, which contain together a population of not quite 26,000. Fourteen of the 24 deaths in Alcester took place in two sub-districts, both of which are needle manufacturing centres. A somewhat similar mortality was registered during 1881, phthisis being held responsible for 24 deaths in the Stratford and Evesham Districts (population 24,597), whereas in Alcester, with a population of 17,387, there were 26 deaths. Mr. Fosbroke regrets that he is unable to give an explanation of this mortality, since the inspection of these needle manufacturing factories does not come within his province. Whether it is in consequence of such trade employment, or that the workmen so generally keep their workshops too hot and "close," he is not in a position to say. This appearance of phthisis is, as Mr. Fosbroke observes, well worthy the consideration of factory inspectors; but it is also still more worthy the attention of the Medical Department of the Local Government, an inquiry by which, on the present state of the question as to the lung-diseasing conditions of various industries, is much to be desired. Such an inquiry was made on a large scale by the then Medical Department of the Privy Council, in 1860-4, and Mr. Simon always recognized the importance of continuing the investigations on the subject. A series of fresh inquiries by various inspectors was indeed begun under his auspices, in the year 1873, but the results were never published, and administrative changes put a stop to their further prosecution. The question is, however, one of no little hygienic as well as practical interest, and deserves exact and systematic study by a skilled investigator.

Carbolic Acid in Typhoid Fever.

At a recent séance of the Soc. Méd. des Hôpitaux (June 9th), a discussion occurred on this subject, provoked by the memoir of M. Desplats, of Lille.

According to this physician, carbolic acid has a very powerful antithermic action, the temperature being very speedily reduced, but mounting after a short time to the former figure. On this account sufficiently large doses are required, M. Desplats carrying the dose to several grams daily. The best method of administering the acid is by enema, from two to three drachms in ten to twelve ounces of water; if the urine becomes dark colored, it will be necessary to diminish the dose. As conclusion, M. Desplats considers carbolic acid a good anti-thermic remedy in typhoid fever, of facile employment and not at all dangerous.

In the discussion which followed Mm. Dujardin-Beaumetz, Damaschino, Rathery, and Siredey, mentioned cases where the carbolized enemeta had been retained and had induced grave collapse, the general temperature falling from 104° to 95°, sweating occurring to such a degree as to cause great anxiety.

M. Dreyfus employed this method for about a year at the Hotel Dieu, and had on several oc-

casions symptoms of collapse ; the temperature remained reduced but about four or five hours, and the constant sweating seemed to wear out the patients. M. Feréol was of the same opinion, the course of the fever being in no degree changed by this medication, the constant sweating weakening the patients, and symptoms of collapse being often apparent. M. Dujardin-Beaumetz resumed the entire discussion by saying that carbolized enemata constituted a powerful antiseptic medication, but produced, sometimes, dangerous symptoms, and should be employed with caution.

Nitrite of Sodium in Epilepsy.

In the *Practitioner*, Dr. W. T. Law relates one case in which the nitrite of sodium proved so beneficial that it would seem well to record it, in order that the drug may have a more extensive trial in this terrible and hitherto intractable malady. The case was a typical one of epilepsy, occurring in a man aged twenty-nine, of a low order of intelligence, of unexceptionable habits as regards drink and morals. The seizures commenced after a prolonged season of excessive study in endeavoring to prepare for a college examination. The appended table gives the result of the various forms of treatment tried:—

Weeks.	Seasons.	Number of Fits.		Total.	Remedies Used.
		Day.	Night.		
14½	Summer.	—	28	28	Brom. of pot. sod. and am.
4½	Winter.	2	7	9	Borax.
23	Winter and Spring.	11	15	26	Bromides with intervals of iron and aloes.
22	Summer.	3	12	15	Bromides with bellad.
14	Winter.	2	1	3	Nitrite of sodium.

The Spread of Infection by Rags.

In the *Practitioner*, Dr. H. Franklin Parsons contributes a very interesting article on this subject, from which we note his conclusions as follows:—

1st. That cases of infection by means of rags do occasionally occur, although, comparatively speaking, not very frequently.

2d. That smallpox is the disease most likely to be thus conveyed.

3d. That all rag workers should be vaccinated and re-vaccinated.

4th. That dust should be avoided. The preliminary dusting of the rags before sorting is to be recommended, but the dust should not be allowed to contaminate the air of the work-room.

5th. That certain measures of disinfection are available, among which exposure to air, fumigation with sulphurous acid, and exposure to hot air or high-pressure steam may be mentioned, each of which has its advantages and drawbacks under certain circumstances.

6th. That in the absence of means by which it may be known whether or not rags have been infected, the cases in which disinfection would appear specially desirable are (*a*) rags from places where epidemics are known to exist; (*b*) rags in a filthy state ; and perhaps (*c*) foreign rags, especially if coming within the two previous categories."

Recognition of Death.

At the recent meeting of the Connecticut Medical Society (Boston *Medical and Surgical Journal*) Dr. G. L. Porter called the attention of the Society to the fear of being buried alive, so prevalent among the public. He made quotations to show how this morbid idea had at times seized hold of the greatest minds. For this reason he wished to impress upon physicians the necessity of familiarizing themselves with the signs of death, so as to be able to allay the fears of overly nervous friends and relatives. After relating the usual signs, the speaker said that the tests offered by the ophthalmoscope were as decisive as any. After death the capillary redness of the disc is lost, and gradually the arteries fade out and become indistinct, until at last they are wholly indistinguishable. If any circulation is maintained, at least a pale redness will enable the capillaries of the disc to be seen.

Dr. Thompson mentioned as a test of death, a small black spot which appears between the iris and the outer angle of the eye, round or oval, enlarges and moves downward and inward until it reaches the iris, when it appears as a concave spot which slowly grows larger. Its cause is supposed to be the changes after death rendering the opaque coat of the eyeball transparent.

Obscure Epigastric Pain.

In the *Lancet*, Dr. Edward B. Gray reports a curious case of obscure chronic epigastric pain, in a man otherwise apparently healthy, which teaches how difficult it is to diagnose duodenal ulcer. The patient, aged 58, had complained of pain "across the pit of the stomach and through the loins" for two years. He was well nour-

ished, appetite good, epigastrium only slightly tender to pressure. He was regarded by his friends as a hypochondriac. Suddenly he vomited over twenty ounces of bright-red blood. He was ordered twenty minims of the tincture of the perchloride of iron every three hours, to keep to ice and iced water, and to remain absolutely at rest on his back. About midnight of the same day he passed between a pint and a half and two pints of clotted blood from the bowel. He passed no more blood, but two days subsequently he was suddenly seized with severe epigastric pain, fainted, and died in a few minutes. At the post-mortem, the stomach and intestines were found full of blood. The sole lesion discovered was a small, deep, ulcer, of the diameter of a split pea, clean punched out of the otherwise healthy mucous membrane of the duodenum. At the bottom of the ulcer was a small perforation in the pancreatico-duodenal artery. The other abdominal organs were healthy.

Ozonized Air as a Hypnotic.

C. Binz has made a number of experiments with ozone, which he published in the *Berl. Klin. Wochenschr.* (1 and 2, 1882). The idea, based alone on speculative reasoning, that ozone as such could never enter the circulation, because it would undergo chemical alteration before it ever could reach the blood, and that in case it even got into the blood it would produce difficulty in breathing, on account of development of oxygen, has been disproved by the following experiments of Binz. For the preparation of ozone he used W. Siemens' pipe for quiet discharge of electricity, provided with the latter by four Bunsen elements and an inductor capable of giving sparks of two ctm. in length. The ozonized air was carried to animals kept under a well ventilated glass globe. The influence of ozone on different species of animals is alike as to the kind, but different as to the degree of effect. In frogs only a slight depression is noted. They act under the influence of ozone as if half asleep. Rabbits, but still more, cats, exhibit a decided depression of the brain. These animals seem deeply asleep, the eyes almost totally closed, and they show no reaction when a tap is given to the glass globe. The respiration appears unimpeded. Investigation has proven that this state of depression ensues before the respiratory passages are anatomically changed.

The experiments on human beings, who inhaled the ozonized air by aid of the usual mask, resulted, after seven to sixteen minutes, in causing sleep. The sensation before the sleep was agreeable, and respiration easy. Just before sleep sets in the person is overcome by a feeling of indifference and seems to be dreaming. Pulse, pupils, and the color of the face are unchanged. With some persons a full sleep could not be induced.

If a large quantity of ozone is inhaled, symptoms of irritation may appear, besides those of depression, viz: irritation in the throat, cough, with twitching of muscles, nausea, and even vomiting.

While these experiments may not possess any immediate value, as the effect of ozone is too transient for the latter ever to be employed for surgical purposes, as nitrous oxide is used, they give us, at least, an explanation why, in cases of sleeplessness and nervous irritability, a sojourn at the seashore, in forests, and on mountains, is so highly beneficial, as in all these localities the air contains a large percentage of ozone.

Treatment of Ophthalmia Neonatorum.

M. Galezoswki's treatment consists simply in touching the conjunctiva with the following solution, using a camel's hair pencil for the purpose:—

℞. Argenti nitrat., gr. x
Aquæ destill., ℥j. M.

After touching with this solution, another pencil dipped in a solution of common salt should be passed over the parts, to neutralize the excess of the silver salt.

Such is the method exclusively employed by M. Galezowski in his opthalmological clinic at Paris; he uses no other means against excessive suppuration, intense chemosis or ulceration of the cornea, if they occur. And yet, out of 400 cases treated in his service, not one eye was lost. Treated in this manner the malady requires from five to six weeks for complete cure.

Tracheotomy.

In the course of a lecture on this subject by the late Professor John T. Hodgen (St. Louis *Courier of Medicine*), the following valuable paragraph appears:—

"Right here is a point to which I wish to call attention. Not infrequently—in fact, as a general rule, when a child has been struggling for breath for hours, it may be, and an opening is made into the trachea so that the air enters easily and freely—there will be, after one full inspiration, an entire arrest of all respiratory movements for

several seconds, so that one who is not prepared for it may be alarmed. But if you watch the face you will observe that even while the respiration is arrested the color is constantly improving; the livid hue is passing away, and the natural hue is returning to the lips and cheeks and brow, and after a few seconds, sometimes as much as half a minute, the respiratory movements are resumed, and the child breathes easily, falling into a quiet sleep. The explanation is apparent; the child was poisoned with carbonic acid, and there was oxygen in the air inhaled by the long inspiration after the trachea was opened.

Tannic Acid in Albuminuria.

The *Lancet* says that in the course of some experiments on albuminuria, Ribbert examined the influence of tannic acid on the excretion of albumen through the renal glomeruli. He found that when albuminuria was artificially produced in two rabbits, to only one of which tannic acid was subsequently given, and the kidneys were excised and heated, to coagulate the albumen, in the one receiving the tannic acid the amount of albumen was much less than in the other. From this and other experiments he concludes that albuminuria of traumatic origin may be arrested by tannin, and that it may prove useful in nephritis, as recommended by Frerichs. He believes that it will be useful chiefly in the earliest stage of nephritis, which he thinks always commences in the glomeruli, and that its use should be continued for a considerable time.

Pneumothorax and Tuberculous Orchitis.

At a recent meeting of the Soc. Méd. des Hôpitaux, M. Vallin presented a patient who had some time before suffered from orchitis, seemingly of traumatic origin. The inflammation in the testicle is subject to frequent exacerbations, accompanied by fever. M. Vallin is of opinion that the inflammation is of a tuberculous nature, for the patient presents all the physical signs of pneumothorax, but unaccompanied by any general symptoms.

This pneumothorax is evidently of tuberculous origin, for there exist evident signs of pulmonary excavations under the left clavicle.

Jaundice with Hydatids of the Liver.

According to most authors on diseases of the liver, jaundice is a rather rare symptom in connection with hydatid cysts in the organ. This opinion is contested by M. Ortiz Coffigny, in his inaugural thesis (*Thèse de Paris*, 1881). He describes three forms of jaundice under such conditions: the first is temporary and due to congestion of the biliary passages; the second, of longer duration, is due to obstruction and inflammation of the canals, and the third is grave or pernicious jaundice. The most common form of icterus in hydatids of the organ is due to obstruction of the ductus choledochus. Jaundice may be of sudden origin or come on slowly. In the first case it is almost certainly a sign of rupture of the cyst into the biliary passages; coming on more slowly, it is almost always due to pressure on the larger canals by a cyst developed about the hilum of the organ.

Special Reports.

NO. VII.—HEART DISEASES.

(*Concluded from page* 109).

ACUTE FATTY DEGENERATION OF THE HEART.

Dr. Samuel West also presented to the same meeting of the Pathological Society (*Lancet*), the following unusual case: It was a specimen of acute fatty degeneration of the heart in a young man aged eighteen. Two months before admission to the hospital he had a mild attack of rheumatic fever, after which he suffered from malaise and slight pain. He got steadily worse and was admitted into the wards. The heart was enlarged, and there were mitral and aortic murmurs. After a week his feet swelled, then jaundice and hæmoptysis occurred, and death soon followed. At the autopsy old cicatrices in the lungs were found. The heart was remarkably yellow and minutely speckled with small, yellow spots, and was so fatty that the oil ran off the cut surface. There were small, recent vegetations on both mitral and aortic valves. The muscular fibres showed fatty degeneration, but no interstitial change. Such cases are not common. Those that have been recorded appear to fall into three groups. The commonest depend upon anæmia, usually chronic, but occasionally acute, such as that caused by repeated bleedings. Then we have the degenerative group, in connection with acute fevers and phosphorus poisoning. In the third group there has been previous inflammation of the muscle; thus, some cases of sudden death in rheumatic fever, with acute myocarditis, have been recorded. The specimen exhibited probably belonged to the third group. The question was asked whether such disease could exist without causing any symptoms except slight malaise, as it was a very

important medico legal point. Decomposition very rapidly gives the appearance of fatty degeneration to the heart. Mr. Doran always found it in the usual rough examination of hearts commonly met with at autopsies. The question was not answered.

INCOMPETENCE OF TRICUSPID VALVE.

Dr. Bedford Fenwick presented a specimen before the Pathological Society of London (*British Medical Journal*). He related the clinical phenomena noted during life, which consisted chiefly in a double cardiac murmur, œdema and marked cyanosis. The mitral orifice was much contracted, while the tricuspid was much dilated. He thought it an instance of secondary tricuspid incompetency. He could only find fifteen such cases so recorded as to be of any use for statistical purposes. He found that stenosis occurred more often in women, and considered this to be due to two causes. First, to the lesser strain on the heart in women, which allowed greater rest to the valves and more prolonged apposition, and secondly, to the fact that the valves are relatively larger in women.

CARDIAC MURMURS IN THE PUERPERAL STATE.

Dr. Angel Money communicated a paper to the Royal Medical and Chirurgical Society (*Lancet*) on this subject. The observations were made on 111 consecutive cases. Murmurs were heard in 84 cases, or about 75 per cent. The great majority of the murmurs were located over the right heart. There were two cases of undoubted structural disease. The patients who possessed a murmur for the most part did not suffer from symptoms referable to the heart. The time of the murmurs was invariably systolic. The murmurs are divided into three sorts. The first (resembling an ordinary endocardial murmur) was most numerous; was of blowing character, soft, usually low or medium pitched, fairly long and heard with almost every cardiac beat, and presented but little variation during the course of its existence. The number of these was 51; 36 were loudest over the tricuspid area, 8 over the mitral area, 6 over the pulmonary, and 1 over the aortic. By tricuspid area he means the fourth left interspace, just a little to left of left edge of sternum. The murmur was conducted to a variable extent. The duration of the murmur was variable. Most commonly the murmur was first heard a day or so after delivery. The most novel and interesting, the tricuspid murmur, is believed not to be due to tricuspid regurgitation. He can arrive at no definite conclusion as to the mode of production. The second kind (friction like) was almost absolutely non-conducted, was heard over a very small area, just above and to left of ensiform cartilage. The murmur seemed superficial, was high pitched and stiff in quality, and was not audible with every cardiac beat. This sort was heard twenty-nine times. The mechanism is probably exocardial friction. The third kind of murmur, the least numerous and the most capricious, was remarkable for its loudness, was very inconstant, *i. e.*, not heard with every cardiac beat, and was very transitory; its area of audition was remarkably limited, it was most frequently heard over one or other base of the heart; it was commonly associated with an excited condition of the heart and pyrexia or mental emotion. Besides pyrexia, excitement and anæmia, this murmur was sometimes associated with râles in the chest, and with a cough, but no sputa. The quality of the sound varied. In many cases it resembled the quality of the sound evolved when a piece of silk, tightly stretched, is scratched with the nail; or like the sound heard when pressure is made on the carotid, in anæmic cases. The murmur was in all cases heard when the breathing was stopped. This murmur was heard sixteen times. The mode of generation of these murmurs was regarded as very puzzling. All the murmurs of the second and third kinds, and the majority of the first kind, were temporary phenomena. Murmurs in the puerperal state are not (as a rule) indicative of cardiac disease. Dr. John Williams has verified these observations in a large number of cases. The murmurs were curious and remarkably frequent, being almost a physiological phenomena. Dr. Finlay said that a point of some interest was the effect which change of posture had upon these puerperal murmurs. He saw a case in which a soft systolic murmur was audible over the whole præcordia, and in addition, a loud, musical systolic murmur over the aortic cartilage, and the second right interspace and the adjacent part of the sternum. These murmurs become almost inappreciable when the patient turned to either side, and disappeared completely when she sat upright.

CONGENITAL CARDIAC DISEASE.

Dr. W. B. Hadden related to the Pathological Society of London (*Lancet*) the following case: The patient was a female child four months old. On admission to hospital the face was pale, the hands and lips livid, the chest expanded badly, respiration 66. Lung resonance in front impaired, but breathing vesicular. No cardiac murmur was heard. Improvement followed the next day. On the third day there was dullness over the left lung anteriorly, and scattered dull-

ness at both bases, with crepitation and rhonchi. Before death respiration was 96 and temp. 101. The heart weighed four ounces, average weight at this age being less than one ounce. Septum between ventricles imperfect above, admitting the whole of the middle of finger. The right ventricle was much hypertrophied, a quarter of an inch thick in some places, its cavity dilated. Musculi papillaries much hypertrophied, as was also the left ventricle. The foramen ovale and ductus arteriosus were practically closed. Pulmonary artery large and the aorta inversely small. It was considered worthy of note that the heart weighed nearly five times the normal amount.

ACUTE ENDOCARDITIS—PYREXIA—EMBOLISM—DEATH.

In the *Medical Times and Gazette*, Dr. H. Ashby reports two cases of endocarditis which he thinks take rank between the simple ordinary endocarditis and the malignant form already discussed. Clinically, the form to which he desires to call attention is accompanied by a systolic mitral murmur, angina-like pain in the præcordial region, pyrexia of an intermittent type, wasting, increasing weakness, the phenomena of inflammatory emboli, and more or less enlargement of the liver and spleen. The first case ran its course in about five months, having what was probably embolism of dorsal artery of foot and later splenic embolism. The second case was cut short by embolism of the left middle cerebral, softening of the arterial wall, aneurism, and finally hemorrhage and softening of the brain. The condition of both hearts was almost exactly similar. The roughened edges of the mitral valves, the numerous fibrinous, tag-like concretions attached, were present in both; also a similar condition of endocarditis extending into the left auricle and creeping up the left wall for an inch and a-half. It is interesting to note that the effects produced by embolism in these cases were not mechanical, alone, but the inflammatory processes set up were due to the nature of the emboli. The red, painful swelling on the dorsum of the foot, the lymph on the surface of the spleen, the aneurismal swelling of the middle cerebral, were silent witnesses to the inflammatory processes affecting the valves of the heart.

MUMPS, WITH ENDOCARDIAL MURMURS.

Dr. John Appleyard (*Lancet*) reports a case of mumps, in which a friction sound was audible over the right base of the heart, near the second rib cartilage. There was no increase of dullness over cardiac region. The parotid inflammation was transferred to the testis and the murmur continued. When desquamation commenced the patient was very weak, and a faint, blowing (systolic) murmur was audible over the pulmonary artery, not appreciably changed by pressure. When the patient recovered, the murmurs disappeared.

RUPTURE OF THE CORONARY ARTERY.

Dr. H. W. Lilly, of Fayetteville, S. C., reports a case of death from rupture of the coronary artery, close to its origin. The patient was a man 50 years of age, of large frame and healthy appearance. He was attacked with severe pain in the breast, and on auscultation, a confusion of sounds that took neither the form of defined râles nor of any of the usual auscultatory signs, was heard. The pulse was quick and intermittent every third beat, respiration labored and shallow, countenance anxious. The man soon became worse, with great dyspnœa and threatened syncope, and died suddenly four hours after he was first seen. The pericardium was found to contain blood clots and bloody serum. The aortic valves were studded with vegetations, and the neighboring part of the artery was atheromatous. The right coronary artery was mottled with small, yellowish-white, irregularly distributed, superficial patches. Just above the semilunar valves the degenerating process was more marked, and a rent was found in the vessel, one-sixth of an inch long, running parallel with its course.

The recent literature on heart disease is very meagre; all that has been written, of interest, during the past six months, has been embodied in this report.

CORRESPONDENCE.

A Discreditable Literary Act.

[We publish, without comment, the letter below, which we have translated from the German original, merely stating that the work was published by a New York house, *contrary* to the author's expressed wish.—ED. REPORTER.]

ED. MED. AND SURG. REPORTER:—

I apply to you, as the editor of a really independent medical journal, to permit me to print in it the following lines, which are certainly not without general interest.

I refer to a translation of my work, *Die Neben wirkungen der Arzneimittel* (The Accessory Action of Medicine), which has been made, directly against my will, by a New York physician.

While I was negotiating with a firm in America about a translation, Dr. Alexander, of New York city, asked my permission to translate it. I declined his request, stating the above reason.

Hence, I was justly astonished, when, recently, I received, through my publisher, a copy of my work, translated by Dr. Alexander, contrary to my expressed wish.

I regret that between Germany and the United States there is no treaty to protect the rights of authors, and I hope this example will aid in showing the importance of one. All the more unpleasant is it when such action is committed by a fellow physician; for certainly the ethics of the physician should be international, and not cease because an ocean separates its members.

Yours respectfully,

DR. L. LEWIN,
Docent in the Berlin University.

NEWS AND MISCELLANY.

Inoculation.

During the course of an address on "Preventive Medicine," delivered before the Tri-County Medical Society by the President, Dr. R. C. McEwen (*Med. Annals*), he paid the following tribute to the discoveries in inoculation of the present day:—

"But the possibilities of the future are unknown. Scientific truths that had their birth in days long past afford no subject for the cynic now, as we live in the enjoyment of benefits from their practical application. It was the growth of a century that developed the wonders of worlds in space and compelled the intelligent mind to accept the Copernican doctrine; yet its author was subjected to the anathemas of the theologian, and his published works incited the superstitious to curse him as heretical. The twitchings of the hind legs of the frog interested the scientist and afforded amusement to courtier and peasant, yet the electric spark encircles the world, and nations are cemented in community of thought and interest. *The future of inoculation* may excite a smile of incredulity, but the seed now sown may become the tree under whose protecting branches the nations to come may enjoy an immunity from disease, only foreshadowed, perhaps, in the present, but waiting the roll of years to become perfected truth, and be added as another blessing from the hand of science, ministering to the comforts and necessities of man."

The Cause of Malaria.

In connection with the National Board of Health, the health authorities of New York, Connecticut, Rhode Island and Massachusetts have undertaken a series of investigations to endeavor to determine the true nature of the malarial poison. The experiments of Klebs, Tommasi-Crudelli, and Sternberg, will be repeated. The laboratory work will be carried on by Dr. W. F. Whitney, of Boston. Physicians throughout the country are asked to coöperate in these investigations, by giving answers to the following questions:—

(1) Has malarial fever in any of its forms prevailed in your town or vicinity during the past year, or does it now prevail?

(2) If so, please state—

(*a*) The number of cases of which you are cognizant.

(*b*) At what season of the year the disease has prevailed.

(*c*) Whether the persons so affected reside near any pond, reservoir, or stream, and if so, how near and in what direction?

(*d*) How many of the persons included in answers to questions, *a*, *b*, and *c*, have had malarial fever in previous years, and how many have been exposed to malaria in other places?

(*e*) Can the disease in any case be traced to the use of drinking water from malarial districts?

(3) Has malarial fever been known in your vicinity in previous years?

(4) Did it exist the year previous to its appearance in your town in any town nearly adjacent. If so, please state where, and how far away?

(5) If malarial fever has ceased to prevail during this or any previous year, state any causes which may appear to you sufficient to explain this relief.

(6) What other diseases have been endemic or epidemic in the town at any time during the year.

Physicians in localities where malarial fever is prevalent need not fear to injure their neighborhood by answering these questions, since such information will not be published at present.

The Toner Medical Library.

Dr. Joseph Meredith Toner has given to the United States, for permanent preservation in the library of Congress, his entire collection of books, pamphlets and periodicals, between 20,000 and 25,000 volumes. This includes the most valuable collection of American medical publications to be found anywhere. Dr. Toner has devoted much time and money to the gathering of this library, and proposes to continue adding to it during his life, and to create a fund to still further increase it after his death. The gift has been accepted by Congress, with suitable provision for its care and preservation.

Items.

—Congress is still disgracefully wrangling over the remuneration of the physicians who attended the late President Garfield.

—A French newspaper reports the deaths of a mother and five children from eating poisonous fungi in mistake for mushrooms.

—Dr. T. Gaillard Thomas has accepted his former position of Clinical Professor of Diseases of Women, in the College of Physicians and Surgeons, New York.

—The important Chair of Clinical Medicine at Vienna—Skoda's chair—lately vacant through the death of Professor Duchek, has been offered to Professor Nothnagel, of Jena.

—Materialists sometimes quote the words of Kant, "Give me matter and I will explain the

formation of a world; but they omit his other words, "Give me matter only, and I cannot explain the formation of a caterpillar."

—Mr. Charles G. Francklyn, in whose seashore cottage President Garfield died, has just founded and endowed a sanitarium for poor children, at Elberon, in memory of his young daughter, Gladys Francklyn, who died recently in Paris.

—Dr. B. W. Richardson, nothing daunted by the work of resisting the drunkenness of the age, has just been presiding at Exeter Hall, over the foundation of a Society for the Suppression of Juvenile Smoking. We heartily wish the Society success.

—In Newcastle, England, a new kind of organization has been established, called the Invalid Loan Society, whose object is the lending of clothing, furniture and such other articles as will minister to the comfort of those who are both needy and sick.

—In Kent, England, a band of young men, it is said, have established a society for the "Protection of the Natural Form of Woman," and, according to one of the rules of the society, bind themselves, "by demonstration, argument and entreaty, to induce their sisters and all ladies who are injuring their bodies for the sake of fashion, to sever the remaining link which connects the present generation with barbarism." By another of the laws the members promise to live a life of protest against the fashions so prejudicial to health.

OBITUARY NOTICE.

GRIFFITH J. SCHOLL, M.D.

The subject of this sketch, Dr. Griffith J. Scholl, departed this life at his old homestead at Hecktown, this county, on Saturday, July 8th, at 7 P. M., at the advanced age of 82 years. Dr. Scholl was a son of Dr. Philip Scholl. He was born at Allentown, Lehigh county, on August 22d, 1800. During his childhood his parents removed to the State of New York, where he spent his younger days and received a liberal education. In after years he took up the study of medicine in the office of his brother, Dr. Henry Scholl, who practiced his profession in Lehigh county, and in due time graduated at the University of Pennsylvania. He practiced his profession in Lehigh and Northampton counties for a period of sixty years, and was a resident of this county over forty years. Dr. Scholl was a successful practitioner, and was more generally known throughout this county, by reason of his advanced age and long service in his profession, than any other member of the medical fraternity. He was blessed with a vigorous constitution and was seldom confined to his bed by illness. Dr. Scholl enjoyed more than a mere local reputation. His counsel was often sought by patients from a distance. In his manner he was genial; in his professional opinion he was discreet; not bigoted or prejudiced. In the sick-room he was calm and collected, and above all, he possessed a manner that gained the confidence of his patient. He was a close observer, a student throughout his life, and as his years advanced his enthusiasm did not diminish. He was honorable and upright in his dealings, kind and truthful to his patients, and always loyal to his profession and professional brethren, never taking part in the petty jealousies and bickerings which too often mar the career of professional men. For sixty years Dr. Scholl followed industriously, honestly, and I believe conscientiously, the calling of his choice, until, two years ago, he was stricken with paralysis, when decided inroads upon his remarkable physique became evident. From this period his health varied, but he continued to practice medicine until about six weeks ago, so that it may well be said he died in harness. On July 3d he had another attack of apoplexy, which ended in death. His sadly bereaved consort, aged 80, survives to mourn the loss of a good and kind husband, three sons and two daughters a kind and affectionate father.

His funeral took place at Hecktown on July 12th, attended by a very large gathering of professional friends and others from all parts of the county. PHILOS.

Bath, Pa., July 12, 1882.

QUERIES AND REPLIES.

W. O. S., N. Y.—Dr. Hamilton prepares sponge for grafting by soaking it in a mineral acid, in order to dissolve out the spicules of lime and silica. He found that the network of keratode so obtained became filled with granulation tissue, and in time became practically a part of the patient's body.

MARRIAGES.

FOWLER—WAUGH.—On Tuesday, June 20th, 1882, in Cohocton, Steuben county, N. Y., in the Presbyterian manse, by Rev. John Waugh, the father of the bride, Thomas B. Fowler, M.D., and Ida Waugh.

FRITTS—WYNKOOP.—At the residence of the bride's parents, in Syracuse, N. Y., on Wednesday, June 14th, by the Rev. E. Van Slyke assisted by Rev. Charles W. Fritts, of Fishkill-on the-Hudson, Dr. Crawford Ellsworth Fritts, of Hudson, N. Y., and Emma Judson, only daughter of Jonathan G. Wynkoop.

GOODNO—HANSBURY.—June 27th, 1882, at the residence of the bride's parents, by the Rev. W. S. Goodno, of Asbury Park, N. J., Charles F. Goodno, M.D., and T. Addie, daughter of H. S. Hansbury, all of West Philadelphia.

GUY—PARRY.—On June 1st, at the home of the bride's mother, by Rev. S. C. Jennings, D.D., S. J. Guy, M.D, of Homeworth, Ohio, and Miss Jeannette Parry, of Allegheny County, Pa.

IREDELL—WILLIAMS.—At the residence of the bride's father, in Trenton, N. J., by Rev. J. R. Westwood, on Thursday, June 29th, 1882, Dr. Harvey Iredell, of New Brunswick, and Miss Emma Williams, of Trenton.

DEATHS.

ATWATER.—At Centre Harbor, N. H., July 13th, after a short illness, Dr. William Atwater, of this city.

BRUSH.—At Norwalk, Conn., July 8th, 1883, Francis V. Brush, M.D.

GREGORY.—At his residence, No. 189 East Seventy-first street, New York, on July 6th, 1882, Dr. Orson S. Gregory.

HOPPER.—At Hackensack, N. J., July 8th, Dr. H. A. Hopper in his fifty-eight year.

LEVIS.—On the 19th inst., Mary E. H., wife of Dr. R. J. Levis, of this city.

WADE.—In New York, Friday evening, June 23d, Dr. Charles H. Wade.

YARROW.—At 4 A.M., on the 17th inst., at his residence, Alloway, N. J., Thomas J. Yarrow, M.D.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

SULPHATE OF SODA IN ACUTE ARTICULAR RHEUMATISM.

BY T. CURTIS SMITH, M.D.,
Of Aurora, Ind.

Sulphate of soda is one of the remedies that had its day of great usefulness, but has been largely, almost entirely, superseded by the less nauseous sulphate of magnesia. Forty years ago Eberle wrote, "this salt is one of the most common and useful purgatives we possess." At this day it is rarely thought of by the profession as a physic to be commonly prescribed where a saline cathartic is needed. I think it to be, in many respects, far superior to the sulphate of magnesia, and when properly administered, scarcely more nauseous to the taste or harsh in its action.

But I will not refer here so much to its general therapeutic value as to what we have found to be its advantageous effects in acute articular rheumatism, and in general muscular aching and soreness.

I am not, as yet, sure of its mode of action, but believe its chief value lays in its power to eliminate urea and uric acid from the blood by its rapid, free, watery, cathartic action. Whether it has any chemical effect to change the excess of lactic acid in the blood, or simply eliminates it, I do not know. I simply know, as a clinical fact, that I have found sulphate of soda to suddenly change the whole character of a case of threatened rheumatism, or of well established rheumatism, in a day or two days, from one of danger and suffering to one of comparative ease and commencing convalescence. I append the report of a few cases in practice, and leave the reader to try this agent as occasion may require, or give it the go by as he may see fit. But I should be happy to have reports from any who fail or succeed with this agent. If it has ever been commended for acute articular rheumatism I am not aware of it.

Mr. R., German, æt. 39, carpenter; works in a dry shop; has been subject to rheumatism, having had several severe attacks that confined him to bed for three to eight weeks. He is an industrious, temperate, good citizen. Came to me early in January, 1882, with a "bad cold" and general muscular soreness, but also with pain and swelling in the right knee and pain in both ankles, rheumatic in character. Said he felt all the symptoms common to his previous attacks of rheumatism, and was quite anxious to escape his prospective weeks of suffering, if possible.

℞.	Sodii sulph.,	℥ iss
	Acid sulph. arom.,	♏xx
	Sacch. alb.,	q. s.
	Aquæ,	℥ viij. M.

Sig.—Take at once, hot, on an empty stomach.

This was followed by ℥ ij of soda sulphate, dissolved in water, well sweetened, every three to four hours. The first full dose produced five or six very free watery discharges, from which he experienced considerable relief. He followed up with the other smaller doses of the same salt, and kept the bowels freely open, but not to the extent of producing any considerable intestinal irritation. Free diuresis was also produced by the remedy. He went to his work two days after commencing the treatment, and had no further trouble.

This was not a case of well established rheumatism, it is true ; but one where every needed premonitory symptom was present.

Miss T., aged twenty-one, of strong, muscular build, generally of good health, but subject to rheumatism, had inflammation of her elbows, then of the wrists; this changed to her right shoulder, then to the right hip and knee. Had been several days afflicted. There was no symptom lacking to establish a moderate case of acute inflammatory rheumatism.

℞. Sodii sulph., ℥ ij
Acid sulph. arom., ♏xx
Sacch. alb., ℥ iv
Aquæ. q. s. to make ℥ viij. M.

Sig.—Drink half at once and the remaining portion in two hours.

This was also given hot, on an empty stomach. It operated freely, producing several large, watery stools. Suffered considerable nausea soon after taking it, but no other inconvenience. This was followed by sodii sulph., ℥ ij every three to four hours, given in plenty of sugar, with lemon juice. Her commencement to recover dated from the free catharsis and continued unto completion, which was about the third day, since which she has not felt any rheumatic pain.

Miss B., aged twenty-four, of full habit, rheumatic temperament, heavy set, strong, muscular build, generally has excellent health, being only subject to chronic granular ophthalmia and a scurfy skin disease, now and then troublesome. In November, 1881, was called to see her; found the ankles greatly swollen, red, and painful. The right knee was also somewhat swollen and tender; right hip painful. Her suffering at night was excruciating. Her pulse was 110, tongue heavily loaded, fever well marked, temperature not taken. Gave her a free cathartic of magnes. sulph., which operated well. Followed this by the attempted free use of salicylate of soda. This produced such free emesis and continued nausea that the dose was necessarily diminished too greatly to be effective. Then used potass. bicarb. ℥ ss, every three to four hours. This was continued fairly steadily for ten days. There was some improvement in the way of diminished swelling and pain, but the disease was still holding its field obstinately. I now gave, for the first time, a full dose of sulphate soda, *i. e.*, ℥ ij, with the acid. arom. sulph., sugar and water, as before described. This was followed by ℥ ij of the sulph. soda, every four to six hours, as needed to keep up steady action of the bowels. In two days she was fairly convalescent and went on to rapid recovery. Since then she has had no return of rheumatic pain.

Was called recently to see Mrs. S. She was a young married lady living in a house with damp cellars under it, and much up and down stair climbing to do. Found her with swollen ankles and tender feet, knees also painful. Sometimes felt the pains in her shoulders and elbows. Had been in this condition for six weeks, not all the time in bed ; indeed, most of the time up, and sometimes trying to do a little work. Her general health was not greatly impaired. Catamenia regular ; bowels fairly free ; appetite moderate.

℞. Sodii sulph., ℥ iij
Sacch. alb., ℥ viij
Aquæ, q.s. ad ℥ xvj. M.

Sig.—Two tablespoonfuls every three to four hours.

On the second day some improvement was noted, and from that date onward it was steady unto complete recovery, which was prompt and quite thorough within a week. She went to her household duties as soon as better, and never ceased to pursue them.

Mrs. D., aged twenty, of light complexion, rather nervous temperament, very active, a hard worker, and very indiscreet as to exposure to heat, cold, or rain. She had an attack of pneumonia in December, 1880, from which she recovered promptly, but in consequence of needless exposure and outdoor exercise contracted a severe cold early in January, 1882. From this there was a rapid development of articular rheumatism, which affected the knees, ankles, wrists and elbows. I found these to be swollen, red, painful, tender, and that motion caused severe suffering ; pulse 120 ; tongue furred white, pointed. There was considerable cough, no appetite, bowels regular, catamenia two weeks since.

℞. Sulphate of soda, ℥ iss
Lemon juice, q. s.
White sugar, ℥ iv
Water, ad ℥ viij. M.

Sig.—Drink half of it hot, on an empty stomach, and the latter half in one to two hours.

This operated well, and was followed by ℥ ij of soda sulph. every four to six hours.

As the pain was very severe at night she had morphia, to control it, but needed none after the second night. Her convalescence seemed to be complete by the fourth day. No relapse.

I find this is a very difficult remedy for some persons to take, on account of the bulk of the dose and its nauseous taste. The former cannot be avoided. The latter can be overcome in a great measure by the use of other agents with it.

The addition of bitart. potass., of lemon juice, or of arom. sulph. acid, ℥xx to xxx, does away with much of the bitter, nauseous taste. Sugar, also, if added very largely, will make it much less disagreeable. But it will nauseate and vomit some persons, prepare it as you may. Full doses are far more effective and less apt to nauseate when given fasting and hot. They also operate far more promptly, *i. e.* in two to three hours, often in one hour. Small doses are easily taken and will bring on and keep up the cathar sis if administered often enough, two to four hours.

I have presented no extreme cases of rheumatism, but some well-marked, moderately severe ones. The remedy either did well for them or they happened to recover quickly while using it. It is not to be expected that this is a specific. I doubt if it is as good as salicylate of soda, but it is easier taken, less depressing and a better eliminator of urea and of the urates, perhaps also of lactic acid. I give this bit of clinical experience for what it may be worth. If a remedy of merit, it will stand ; if not, it deserves to fall.

PRACTICAL NOTES ON THE DIAGNOSIS AND TREATMENT OF ULCERS.

BY G. HALSTED BOYLAND, A.M., M.D., ETC.

(*Concluded from p.* 117.)

Analogous to other dyscrasiæ, it has been essayed to heal syphilis partly by general influences brought to bear upon the process of nutrition, partly by means of specific alteratives. If the first way is chosen, the patient's nourishment must be reduced to such a minimum as the actual sustenance of life will permit, and at the same time he shall drink freely thin and purging drinks; the secretions should be, as much as possible, and in various ways, stimulated by diuretic and diaphoretic means. It is hoped in this manner to hasten the change of tissue and to carry out from the body or destroy the disease germs (?). The principal representatives of this method of treatment are the bitter-salt cures of the English and Zittmann's decoction. Many, indeed, ascribe to the latter a more specific effect.

The most vaunted specific is mercury, among the preparations of which the sublimate, hydrargyrum bichloratum corrosivum, and gray salve for inunction, unguentum hydrargri cinereum, have long been celebrated as anti-syphilitics. Yet none of the numerous preparations of quicksilver guarantee against a return of the evil. The best results are probably attained as follows: Rest in bed, in a warm room, with good nourishment, and for a period of three weeks inunction three times daily of from 1–2 ℈ of unguentum hydrargyri cinereum. The former hunger and purgation cure recommended by Lourrier-Rust during inunction helps the healing of syphilis not at all, but endangers to a considerable degree the health of weak individuals.

Salivation, that was earlier considered useful and necessary, is now, and with right, to be strictly guarded against as harmful, and as a condition that can have in its suite often terrible consequences. If the mouth be daily rinsed from eight to twelve times, with a solution of chlorate of potash, one part to fifty of water, and the patient swallows a solution of the same salt, twice as strong (four times daily a tablespoonful), salivation is generally effectually headed off, even in the most energetic inunction cure. A mercurial eczema will appear sometimes during the inunction, and especially in tender skins; this is not in the least to be regarded as a critical eruption, but only as the result of irritation to the skin caused by the mercury. In order to spare the patient this annoyance the place of inunction should be changed as often as possible. It is best to commence, for instance, with an arm, the next time taking the other; then the four quarters of the body successively, and so on, until the whole body and extremities have been rubbed. Then, after a warm bath, commence from the beginning again. The internal exhibition of sublimate was formerly fraught with difficulties, although its efficacy was recognized, and, indeed, it must be admitted that in taking this preparation by mouth there is an uncertainty, on account of its liability to reaction, as well as on account of its injurious influence on the mucous membrane of the stomach, even when the patient is well nourished. Nevertheless, I have seen the most happy results in the treatment of secondary syphilis from the employment of the following:—

℞.	Hydrarg. bichlor.,	gr.j
	Guaiac. resin.,	grs.c
	Gummi. muci., q.s. m. f.	pil.xxiv.

Sig.—Take two pills three times a day, immediately after meals.

This treatment must be continued for some weeks. Or

℞.	Hydrarg. bichlor.,		
	Ext. opii,	āā	grs.v.
	Glycerine, q. s. f. l. a.		pil.c.

Sig.—Two pills, three times daily; and continue for a long time.

One case in particular, of very old syphilis, from

among very many others, shows the good effects of minute doses of quicksilver, extending over a long period. This patient was subject to the usual syphilitic headaches, and had on his nose, and arm, and back, several ulcers that had been very obstinate in treatment. They were about the size of a dime. After the pills had been administered for a fortnight they began to take on a more healthy appearance, and finally healed, at the end of four weeks. No potass. iod. was given, either during or after the administration of mercury, and no other treatment of any kind ordered. The patient, however, of his own accord, has daily, morning and evening, rubbed the ulcers with imported white castile soap. The alkali probably did no harm, to say the least; and perhaps, theoretically, some good, but this single circumstance would not warrant any opinion, pro or con, except in so far as the cleanliness of ulcers in general is concerned.

Dr. G. Lewin's* method has received great approbation and wide practice. Fearing, perhaps too much, the inunction cure, and the internal exhibition of sublimate, he introduced, and has now carried out in several thousand cases, the hypodermic injection of sublimate. Lewin uses for this purpose the following solution:—

℞. Hydrarg. bichlor., corrosiv., gr. ij–v
Aquæ destill., ℥ j.

with a modified Pravaz-Luër's syringe, containing 36 grains of liquid.

As the stick of the lancet-like point, as well as the injection itself, is painful, those places on the body are chosen for injection where the cutis is less sensitive, namely, on the back. The quantity of sublimate injected, once daily, varies, according to the requirements of a given case, between one-tenth and one-third of a grain. To insure entire disappearance of existing syphilitic symptoms, the whole quantity necessary was found to be from one and one half to three grains. The results of this treatment were of the most favorable character, both as regards the direct influence on the disease and the guarantee against recidiration. As an especial advantage of this treatment, is to be noted, that the patient is not obliged, during it, to remain either in his bed or even his room, if the weather is at all good, and can, therefore, go about his business and live as he otherwise would.

With the principle fixed, the quantities given, and an ordinary hypodermic syringe, the general practitioner has in his hands, probably, the very best treatment of syphilis. The employment of iodide of potash with mercury would, in our opinion, be better omitted. Being a powerful reabsorbent, it would affect the slow alterative action of mercury; but in inveterate syphilis and after repeated, irregular and very free use of mercury, iodide of potash is of great service. It is, however, useless to begin the treatment of lues universalis with it. If employed too long and in too great doses, it has just as bad, though, perhaps, less apparent, consequences as the analogous treatment with quicksilver. But the certainty of the result is much greater if we begin with a very cautious mercurial course, in a warm room and with good diet, and later attack any recidiration with iodide of potash, or when this fails us, with Zittmann's decoction, raised in strength according to the condition of the patient. With reference to diet, only so much stress was laid upon it a short time ago, as regarded the avoidance of all exciting, and the diminution of plastic (nitrogenous) food, it being deemed necessary as an adjuvant to the mercurial treatment. Such a scanty diet, however, is only suitable to over-nourished or, at most, very well nourished individuals, but can only retard instead of helping the cure in the general run of patients; it is especially to be avoided in such as are weak by nature or from former illness, privations, or, perhaps, medical treatment. Here, also, the physician must discriminate. Especial attention should be paid to the place where the patient stays during treatment. Although a warm room is deemed useful, even necessary, to the patient, it is certainly not intended to say that such a room needs the air less than others, or that, in general practice, a patient should be kept in a small, close room, without sun. Fresh, pure air, and a sufficiently frequent change of air, are as necessary to syphilitic patients, no matter what treatment be adopted, as to others. Finally, the ordinary psychical tendency to melancholia during the treatment of syphilis, more than in most chronic evils, should receive strict attention and be treated by moral counteraction—pleasant books, cheerful words, innocent amusements, etc.

The therapy of scurvy consists, above all, in removing the ætiological features. Good food, especially fresh meat and fresh vegetables, acid drinks, lemon syrup, lime juice, citric acid, enlivening and tonic medicines, tinctures of iron, soon bring about an improvement, and in cases that have not advanced too far, a cure. Unfortunately, just where scurvy is present in great mass, on ships and in war hospitals, it is least in the power of the physician to procure the

* Charité-Annalen, Bd. 14. Die Behandlung der syphilis mit subcutaner sublimat-injection. Berlin.

most important of these remedies. Although the prevalence of scurvy in armies, in time of war, is generally conceded to be a common occurrence, yet I never saw a case of it during a short service in the army during the great war in America, nor one during a service in the French army, extending throughout the whole duration of the Franco-German conflict; moreover, during a sea voyage of several months' duration, there was not a single case of scurvy on board the vessel, although our only food was in hermetically sealed cans and salt beef. On the other hand, I did have a case of the nature of scurvy on land, and in private practice, brought on by eating too much ham and salt beef. The patient had such a craving for salt that he even employed it on ham and salt beef. The symptoms disappeared slowly after the employment of alkalies, such as soda bicarb., etc., ten grains three times daily, with a dose of calomel at night; saline aperients were also given in the course of treatment. But, in our treatment of ulcers, we must give a very prominent place to topical therapy, as well with dyscrasic as idiopathic ulcers. The question was at first freely discussed, whether, indeed, all ulcers, especially those that have already lasted some time, ought to be healed. Do we not, by suppressing them, take away from the organism a healthful drainage, as it were? As far as healing the dyscrasic ulcer is concerned, no one will be in doubt as to its advisability; but in those that owe their existence to topical causes, and are sustained by the tension of a scar, by atony, etc., it is first necessary to remove the local causes; and this is, perhaps, not advisable, because "a general affection exists, for which the ulcer serves as a kind of drain, and which, after suppression, would make itself felt in a vicarious and dangerous manner." On this point let us hold fast, before all, that we shall not succeed in healing an ulcer of this kind until the general affection is removed. When we allow to nature so great an intelligence as to form a useful, so-called drain, why should she be so simple as to let it readily be closed up. There is, to day, no doubt that the chance cases in which the rapid healing of an old ulcer is recorded are to be explained in quite a different way. Compare "fistula." The main fact is that, in general, old ulcers do not heal rapidly, and that recidiration, even after perfect healing of an old ulcer, takes place uncommonly often. The loss of substance at the place of the ulcer is always filled up by cicatricial tissue. This develops itself on the one hand slowly, and can, on the other hand, through many more insignificant influences, be brought to necrosis easier than normal tissue.

It is also certainly possible for a dyscrasic ulcer to heal without the aid of science, as has already been mentioned in speaking of syphilitic ulcers, of course, without guaranty that with healing of the ulcer the dyscrasia is removed. Then, again, it has been shown, by precise observations, that an ulcer, on account of strictly local difficulty, could not heal when there was no dyscrasia in the body of the patient, or long after it had ceased to exist. The removal of this local difficulty, in all cases of ulcer, has become, in modern times, the principal exercise of the general practitioner, as well as the surgeon. If it is a question of simple ulcer, the treatment employed in suppurating surfaces is all that is required—cleanliness by means of sponging with tepid water, and the application of compresses wet with lead water. Above all, the part upon which the ulcer sits must have rest and be protected from external injuries. Care must, therefore, be taken not to change the bandage too often. The *hypersthenic ulcer* demands, in general, an antiphlogistic treatment. Moistened, warm cataplasms, and oft repeated lukewarm baths render, in most cases, the best services. Patients more seldom bear the application of cold. *Asthenic ulcers* require the exhibition of irritating and astringent measures, notably aromatic fomentations and baths. In *putrid ulcers*, after chemical disturbance of the gangrenous parts by caustics, the disinfectants find a place, then charcoal bandages, or when the locality permits, permanent baths and irrigation. If the inflammatory reaction necessary to healing is wanting with this, we must try and induce it by irritating means (excitantia). *The callous ulcers* demand, for the purpose of removing the chronic inflammation upon which the callosity rests, a position of the part such as will tend to aid the flowing off of the liquids, also the application of cold, and later a compressive bandage, under the influence of which the exudation that has already become fast, will be most easily resorbed. In the application of such a bandage I have found strips of adhesive plaster of the greatest service; also in *fungous ulcers*, in which it is especially necessary to regard the ætiological conditions. *In œdematous and varicose ulcers* our therapeusis is chiefly to be directed against the œdema and varicosity of the veins. Here, the tinct. ferri perchlor., and tinct. digitalis, ten drops of each, alternately, three times a day, with compression, are our best means. The two last forms, especially on the lower leg, where ulcers occur

uncommonly often, are among the most common complications; for this reason we may not unfrequently throw the treatment of these ulcers with that of varices together. The elastic stocking is our mainstay with them. Finally, it is of great importance to remove any malformations that may show themselves on an ulcer, namely, sinuosities whose removal is best accomplished by amputating the undermined borders, so far as they are of considerable thickness; at least they must be slit up. This method is preferable to all others.

The plan of encircling an old torpid ulcer is also excellent. It consists of describing a circle with a razor or other sharp instrument, just outside the demarcation line of the inflammatory zone surrounding the ulcer. The rationale of this proceeding has already been explained in this article. A razor is probably the best instrument, especially one with a heavy back, as by its own weight it will make the incision just deep enough, if guided by the hand of the practitioner.

The signal of beginning to heal is the change of the secretion into good pus of proportionate quantity. Thus the ulcer is gradually changed into a suppurating surface that then cicatrizes in the usual manner. There is a pathological reciprocation here, for just as an ulcer becomes again a suppurating surface, so a suppurating surface, notably a wound, can change into an ulcer, especially when a considerable loss of substance has taken place. As soon as cicatricial tissue can form, a suppurating surface is made out of the ulcer; as long as there is no cicatricial tissue formed, ulceration continues. As regards technical distinction, recent authorities accept the following four stages in the healing of ulcers: 1. Stadium detersionis. 2. Stadium suppurationes. 3. Stadium granulationis. 4. Stadium cicatrisationis. The definition of these by no means sharply separated stages is indicated by the natural process of healing. This embraces ulcers in general, lupus included, in the treatment of which the dyscrasic as well as the local therapy must be kept in mind. By combining both, and attacking the constitutional and local diseases together at the outset, the quickest and best results are obtained. Cod-liver oil, preparations of iodine (hydrarg. bijod. rubrum) and the anti-scrophulosa in scrofulous lupus, the anti-syphilitica in syphilitic lupus. If the clinical history of lupus can be accurately traced, a taint of such kind will usually be found as its author. The same principles apply here; constitutional treatment alone, while improving the general condition of the patient, will not remove the ulcers, which local treatment alone might do, but which it will be more likely to accomplish when aided by constitutional treatment. Among the salves most useful are: one scruple sulph. jodat. to one ounce of lard, and one to two scruples of iodine to one ounce of mercurial ointment. If these do not produce other results than a superficial irritation, we must at once employ caustics, the choice of which is immaterial. The quickest, surest, and least dangerous, is the following; zinc chlor. one part, to two parts of meal. Chloris. of gold is certainly, at least, as efficacious, but too expensive. Burying small pieces of caustic potash in the lupous tissue also causes a thorough breaking down of it. The employment of argent. nit. requires more time and is more painful. The galvano-caustic leaves other therapeutic measures far behind; it is so easy to burn the little ulcers with the blunt point of the instrument. The actual cautery is seldom good to employ, because there are unavoidable heat rays which spread to the surrounding parts, and it is on the face that we find a very large proportion of lupous ulcers. If the locality permits, the knife merits the first place, especially where, by a little plastic management, it is possible to replace the part carried off. But as long as the neighboring parts show any traces of lupus it is better not to undertake any plastic operations, on account of the danger of recidiration.

Hebra considers exfoliative lupus as an idiopathic local disease, and uses only local treatment. He readily agrees with us, however, as to lupus serpiginosus, lupus hypertrophicus and exulcerans.

We see no reason to abandon our ground that all lupus will be found, provided the clinical history can be got at, to rest upon a dyscrasia.

I have found, in my own practice, tar ointment, as prepared officinally, an excellent dressing for syphilitic ulcers, in conjunction with a mild mixture of mercury and sarsaparilla internally. The tar salve acts as an irritant, and inflames the ulcer at the first, but this soon yields to an agreeable reaction. I order it to be applied, morning and evening, on a piece of soft linen, kept in place by a bandage. In one case of syphilitic ulcer of the ankle, which had been much inflamed by over exercise on the part of the patient, a middle-aged married man, and father of several healthy children, still living, one application of tar salve seemed to increase the inflammation, but in a few hours this disappeared, and after a second application, the inflammation was reduced to a very great extent, the size of the ulcer

d minished, and its general appearance became more healthy. This patient did not consult me but twice. Several months later I met him. He was going about with free use of his ankle, not complaining of further local inconvenience, and much improved in general health. Several years had elapsed, the patient told me, between his first syphilitic infection and the appearance of the ulcer. About its development and direct exciting cause, he could not give me exact data.

STRICTURE AT THE SIGMOID FLEXURE OF THE COLON.

BY C. H. MERRICK, M.D.,
Of Seattle, W. T.

Mrs. R. is a delicate lady, twenty-seven years of age. For some time she has been troubled with constipation and hemorrhoids. Previous to my visit to her she had been treated by two gentlemen of the homœopathic school, for constipation. What medicines and potencies they used I do not know, except that the gentleman employed previous to my taking the case admitted that, having no hope of her recovery, he had given her large doses of morphine, "to keep her quiet." At my visit I was informed that it was then twenty-one days since she had a movement from the bowels. The abdomen was not so very tender to the touch, but very tympanitic; the flatus in the small intestines distending the abdominal walls so that the patient looked like one at full time for confinement.

The impression on the mind of my predecessor was that there was intussusception of the intestines. I thought not, as I discovered the descending colon, for six or eight inches above the sigmoid flexure, to be filled with hardened fæces, and learning that she had been treated to large doses of morphine for more than a week, I expressed the opinion that it was a case of impaction of the natural excrement of the bowels.

As I write for the benefit of the medical profession, I will give a brief sketch of my treatment of the case. Of course, I prohibited morphine. I gave sodæ et pot. tart., rhamnus purshiana, sodæ sulph., and hyoscyamus, as laxatives, keeping her quiet with chloral hydrate and bromide of potassium. To subdue fever and inflammation I depended upon aconite, gelseminum and digitalis. Let me remark here that these remedies were used singly; I avoid compounds as much as possible in all my practice. Of course, the usual external applications were made, and enemas occasionally repeated, although she had been, previous to my first visit, nearly worn out by attempts to distend the bowels with water. A half dozen times or more I attempted to introduce a rectal tube, but owing to the great pain which it caused I failed to insert more than a few inches of the instrument. The temperature of the patient never exceeded 101°, generally ranging from a fourth to one degree below or above normal heat. Her pulse ranged from 110 to 140, and at times with other symptoms, indicating a speedy dissolution of soul and body. A surgical point of some interest must be mentioned here. Deeming any rational procedure justifiable to relieve her intense agony, I did not hesitate to plunge an aspirating needle into various distended intestines as they bulged up beneath the thin walls of her abdomen. Eight times, and in as many localities, I repeated the operation, in each case causing the intestine to collapse and giving the patient temporary relief. No peritonitis or other unpleasant result followed these punctures.

I wish also to correct another popular impression which I have known some physicians to assent to. The picking at the bedclothes, grasping at invisible objects, *muscæ volantes*, is generally thought to be an infallible sign of a fatal termination. So, also, is stercoraceous vomiting, subsultus tendinum and singultus. All these ominous symptoms were present for several days, yet the patient is now convalescing most favorably.

On the twenty-seventh day I discovered that the plug of hardened fæces in the transverse and descending colon had softened, so that by massage and taxis I dislodged the mass, moving it upward. I then became convinced of what I had suspected, that there was a stricture at the sigmoid flexure of the colon. I sent for Dr. G. A. Weed, who kindly came to my assistance. He advised a renewal of the attempt to insert the tube, under anæsthesia. He administered the "A. C. E." mixture, and I insinuated my fingers and finally my hand into the rectum, and found it a complete *cul de sac*. I soon discovered a small depression not larger than the os tincæ of a virgin womb. Into this I wedged my index finger and then the middle finger, and spreading my fingers to the utmost of my strength, managed to dilate the passage. I then inserted the flexible tube and withdrew my hand. With a stomach pump I now threw in warm water and then allowed it to escape through the tube. By repeating this operation a gallon or more of fluid fæces was withdrawn. The patient soon fell into a quiet sleep, and her progress to recovery, to this date, has been rapid and satis-

factory. The sphicter ani, so put upon the stretch, is recovering its power. The dilated stricture continues open, and strong hopes are felt that another operation to insure its patency will not be required.

I have no desire to say a word disrespectful of my homœopathic friend who preceded me in the case. I believe, in certain kinds of work, a gimlet and tack hammer are useful tools. I prefer to have a whole chestful to select from, and in this case my friend had certainly, in the use of morphine, borrowed our sledge hammer and was using it in rather a wild and desperate manner.

A DENTAL HERESY.

BY HENRY S. CHASE, M.D.,

Of St. Louis, Mo.

Like the professions of medicine and divinity, that of dentistry has at last its heresy. It is called the "New Departure" by the dental journals, though who first gave the movement that title is not known. The New Departure is not only a new method of practice, but the theory upon which the practice is based is also new.

As this practice involves methods of saving the natural teeth entirely diverse from the old methods, it may not be uninteresting to glance at its history.

About eight years ago Dr. Fletcher, of England, announced in the dental journals that nine out of every ten gold fillings leaked. That is, the gold plug did not exclude saliva from the cavity of decay in which it was placed to do such duty. An "experimental dental club" in this country demonstrated the truth of the assertion, much to the disgust of its members.

About this time Dr. Palmer, of Syracuse, N. Y., asserted, in the *Dental Cosmos*, of Philadelphia, that the failure of operations with gold lay mainly in its incompatibility with dentos (tooth bone), forming with the latter a galvanic battery of low power, but of constant operation, of which gold was the negative element of the battery, and dentos the positive. As is well known, it is the positive element that suffers chemical disintegration in the battery.

The entrance of saliva under and around a gold plug in a tooth gives the condition of a constant battery, and consequently, a constant decay of the tooth at that point.

Dr. Chase, of St. Louis, and Prof. Flagg, of Philadelphia, early took hold of the subject, and not only made extended investigations themselves but also interested several gentlemen, who are teaching physical science in well known colleges and universities. The latter confirmed the theories of the "New Departure Corps" by experiments in the line of metallurgy and magnetism. The writer has not the liberty to publicly give the names of these gentlemen, but the editor of this journal has them.

When the results of these investigations were given to the dental profession through its magazines there ensued great excitement, and for six years there has been war between the "New Departure men" and the "gold men." But the present condition of the heresy is well put by an eminent dentist, and president of an important dental society, in the following words, written in a private letter, recently, to Professor Flagg:—

* * * * "I feel, as I know do hundreds of others, that I owe much to you and your confreres, Drs. Palmer and Chase, for the work you have done in making more plain and practicable the great business of *saving teeth*, and although it is still the fashion to deride the 'New Departure' doctrines in the dental meetings, I know of none who have not been influenced by them; and I believe there are not many who do not apply them at this day, in practice."

The outcome of the whole heretical movement is this: gold as a filling material takes an inferior position.

During the eight years that this subject has been under discussion, the thought of the profession has been turned toward the discovery of materials that would be in more electrical harmony with tooth-bone than gold is, and also make water tight or saliva tight fillings; and there has been great success in this line. Alloys of metals have been made, which, being amalgamated, make not only water-tight plugs, but even those which will exclude alcohol as a test of completeness, and which have a tint more in harmony with the color of the enamel than gold has.

Besides metallic alloys there are chemical combinations made at the instant of introduction into the cavity of decay, which are in comparative electrical harmony with dentos, and are, indeed, the positive element in the dental battery.

There are other heresies that need not be described here, belonging to the New Departure, which tend to the preservation of the dental tissues, and which materially simplify operations.

The whole movement is one of immense importance to the public, and I think this is the first time it has been made known to them in print, excepting through dental journals.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM GOODELL, M.D.,

Professor of Clinical Gynecology in the University of Pennsylvania.

Reported by Wm. H. Morrison, M.D.

Cystitis—Dilatation of the Urethra.

Gentlemen: The first case that I shall bring before you to-day is one of cystocele. Let me first read her history. She is twenty-one years of age and has had two children, the youngest of which is eighteen months old. Both her labors were very difficult. They were instrumental labors. Since her first labor she has been troubled with irritability of the bladder. After the second labor matters became worse, so that she is now in a very wretched condition. She suffers from frequent micturition, burning in the act of passing her water, and constant vesical tenesmus. The urine contains pus, and frequently blood. She has purulent leucorrhœa and laceration of the cervix. There is a good deal of pain caused by touching the bladder. She is at present nursing her child The urine has been examined, and contains a good deal of albumen, which I fancy is owing principally to the presence of blood and pus. There appears to be no renal trouble whatever.

Here, then, is the history. She has passed through various courses of treatment. She has consulted a great many physicians, and taken any number of medicines, medicines chemically adapted to the condition of the urine and diuretics, without any relief whatever. She says that she has to pass her water every half hour. This I think is an exaggeration, but if she is obliged to get up every hour during the night, you can understand what a tax it must be on her strength. In addition to this strain on her system from the irritability of her bladder, she is nursing her child. I have seen the most woe begone patients whose only trouble was this condition of their bladders.

It is barely possible, although I have no evidence in regard to the matter, that the traction made with forceps was not made in the axis of the superior strait or in the axis of the curve of the pelvic canal. If the physician had drawn the head forward too much, it would have pressed the bladder against the pubic bone, setting on foot a cystitis. I have often seen inflammation of the bladder caused by the way in which the head is drawn out. As I say, I have no right to make such a supposition in this case; I simply refer to it in order to educate you in this matter. After you have applied the forceps, you should draw the head down in the axis of the pelvic canal; but although you may deliver the head scientifically, you will often find that the woman is unable to pass her water. This may be due to one of three causes. In the first place, the mucous membrane of the urethra may have become swollen, from the pressure of the head upon it; in the second place, she may have lost power over the extrusor muscles of the bladder, they being temporarily paralyzed; and in the third place, the long labor has so weakened her that she is unable to cause the urine to flow by contracting the abdominal muscles, which are really the chief extrusor muscles of the bladder. For these reasons we may, after a difficult labor, find the woman unable to pass her water. It should always, under such circumstances, be drawn; but you are young, you have never passed the catheter, and you do not care about doing it. The woman may tell you that she is unable to make water. You say to her "It will come around all right after a while. I have known physicians leave the bladder go thirty-six hours without emptying it, and often an incurable cystitis follows this lack of common sense. In such cases, always pass the catheter, on your finger if you can, but if you cannot, call for a light. Never allow any time to elapse after the woman has begun to desire to pass her water. After a tedious labor, and often after an ordinary one, there is such flaccidity of the tissues that the bladder will become enormously distended without the woman complaining.

Suppose that cystitis has occurred; what will you do? The water should be drawn, either by yourself or the nurse, or if you live four or five miles from your patient you may use a self-retaining catheter. This Skane-Goodman is the best. Then you should put a suppository into the rectum. A very nice one contains—

℞.	Extract opii,	gr. j
	Extract belladonnæ,	gr. ⅓.

One-third of a grain of the belladonna may seem very small, but many women are so impressible to its action that you have to begin with a small dose. In these cases I often give belladonna by the mouth, in the form of the sulphate of atropia. A poultice may be put over the lower part of the abdomen, and in the course of a few days you will find, in the majority of cases, that the cystitis has disappeared. But, if you do not treat the case properly the trouble may run on until it becomes as bad as it is in this woman.

I shall, in the first place, examine the womb. I find that there is a tear on the right side of the cervix. This leads me to infer that the head presented in the occipito-posterior position. This may have been one reason why the forceps were applied. There is also a small tear on the left side. I do not find any evidence of cellulitis or of the presence of a tumor. The vagina has lost a great deal of its elasticity. This may have resulted from overstretching during labor.

I wish to determine next whether or not the uterus is doing any mischief. I therefore pass the sound. It shows that the womb occupies a very good position. It is a little lower than it should be. It measures three inches, but after two labors, especially if there was laceration of the cervix, we should expect some subinvolution.

I intend to dilate the urethra, but before doing so, I am going to wash my hands, for I have been using my finger to examine the vagina, and I do not want to get these discharges into the bladder. This mode of treatment (dilatation of the urethra) is a very successful one. It is not infallible, but in the great majority of cases it does cure, and even where you do not absolutely cure

the patient, you usually make her so comfortable that she is very grateful.

How will you proceed to dilate the urethra? I take a dilator (Ellinger's, with a slight modification of my own) and gently distend the urethra until it is large enough to admit the tip of my little finger. Then with my little finger I carefully dilate the canal, trying to do no harm. I have frequently torn the margin of the meatus and this rarely heals up, but this does no harm, although I have seen considerable bleeding come from it. I operated once in this hospital, and in going to the ward some time afterward, found that the woman had lost considerable blood. The hemorrhage was easily checked by Monsel's solution. In another case which had a very bad cystitis, I operated before the class and greatly relieved her. She afterwards became pregnant, and the pregnancy started up the old symptoms. I again operated, and tore the anterior part of the meatus. The bleeding was so considerable that I could not check it with the ordinary styptics. I put my finger on it, but as soon as I removed my finger the bleeding returned. I then put in a stitch, down to the pubic bone, including the bleeding point, and this checked the hemorrhage. The bleeding in this case was due to the fact that in pregnancy the veins of this portion of the body are in a more or less varicose condition.

Before using the dilator I shall pass in the sound, to see if she has a stone. If I introduced the sound without ether she would suffer excruciating pain. I feel that the bladder is much contracted and roughened by its contraction and by the prolonged cystitis. There is an erosion of the mucous membrane, as is shown by the presence of blood in the urine. I do not feel any stone.

I shall now pass in the dilator. Although she is snoring under ether she flinches when I dilate. A little urine tinged with blood flows out. As I have said, this is a very successful operation, but I have failed. In one of the worst cases that I ever saw the operation failed. In this lady the cystitis was caused by traveling all day in a stage coach where she did not have an opportunity, with decency, as she thought, to empty her bladder. By and by, when she arrived at her stopping place and had gone to her hotel, she found that she could not pass her water. A physician was sent for, but he was absent, and this caused a longer delay. When he came he had a good deal of difficulty in introducing the catheter, because the distended bladder had caused retroversion of the uterus. From that time (she was then a young lady) until the age of forty-five, when I first saw her, she was a martyr. In her case I dilated the urethra without a particle of benefit.

There is some bleeding here, from a slight lateral tear, which I never saw before in performing this operation. In my book I say that you can dilate the urethra to the size of the forefinger. I want to retract that, for I have had one case in which, after dilating with my forefinger, some loss of control over the bladder followed. My index finger is of medium size; some may have a smaller one and others a larger one. I think, therefore, that if your index finger is of large size, you had better limit yourself to the little finger, using the forefinger only when the dilatation with the little finger fails. I have had to operate in a case where the physician had introduced his thumb. The result of the dilatation being that she had entire loss of control. In the course of a week or two I expect such a case to come into the hospital. Even in the case to which I have referred, where there was this stillicidium, this loss of control, the woman was so much benefited that she did not complain of it.

Now this operation was not original with me. I do not want you to get that idea. I think that it was Mr. Teal, a surgeon in Birmingham, England, who first brought forward some cases of this operation and he was soon followed by others.

What is the rationale of this operation? I cannot tell you positively.

One way that I account for it is this: That the irritability of the bladder produces spasmodic contraction of the muscles of the urethra, causing them to increase in size. We have no true sphincter muscle in woman, but we have a series of little fibres all the way from the meatus externus (the meatus externus has no muscular fibres) up to the neck of the bladder. These little fibres, in consequence of the irritation of the bladder, may have increased in size and strength. You know that if you have an irritable eye, the muscles are continually twitching, and soon become enlarged.

There is another condition in which dilatation would do good. There may be, in these cases, a little fissure at the neck of the bladder. Fissure in ano is very common in women. By the way, do not forget to examine carefully the rectum of a woman who complains of pain when the bowels are moved. Where you find one man with a fissure, you will find nine women. There are two reasons for this: first, the constipation which is common in women; and second, the injuries sustained during labor. I am disposed to think, while I cannot state it confidently, as I have never felt it, that we may have a little fissure at the neck of the bladder. In these cases you will find a painful spot just at the neck of the bladder. Higher up you do not get the same kind of a pain. If this condition is due to a fissure at the neck of the bladder, we should expect overstretching of the urethra to cure it, just as overstretching the sphincter ani muscle cures a fissure in ano.

While I have been talking I have also been working. This urethra has dilated very easily, and I do not find the bladder as rough as I had expected. As I have gotten my little finger in so easily, I shall try to pass my forefinger. There is a little tear on the left side, but that will heal up readily, as it is within the urethra. I shall use my left forefinger, for, as I am a right-handed man, my left hand is the smallest. My forefinger goes in quite easily.

I expect that by to-morrow this woman will experience an immense relief. You would suppose that she would suffer great pain the first time she passes water, but she will suffer far less than she did before the operation.

Dr. Baer tells me that she has had injections into the bladder through a double canula, but I

think there is nothing so unsatisfactory in responding to treatment as a chronic cystitis in woman or in man. I am not cognizant of any case cured by injections through a double canula.

I now have my finger in the bladder, and if there was a stone I should feel it, unless it was incarcerated and so small that I could not find the point where it was lying. I never had a urethra in which I introduced my finger with more ease than this one. I have not ruptured a fibre inside. I feel it pinching my finger as I withdraw it.

Immediately after the operation I introduce an opium suppository, so that she will be under the influence of the opium by the time she recovers from the ether, for women are always in a demoralized condition when they come out of the ether. I introduce an opium suppository after all operations on this part of the body, even after the painless operation for laceration of the cer vix, for there is some soreness here, from the pressure on the perineum with the speculum.

Let me give you a few remedies useful in cystitis in its acute form, at which time it should be stopped. In the first place, the use of the suppository of opium and belladonna referred to ; or, as women are easily affected by belladonna, I sometimes put the belladonna in one suppository and the opium in another. I can then push either as may be necessary. In the second place, never allow the bladder to become too full. In the third place, be very careful, when passing the catheter, not to allow the catheter to be introduced to its whole extent, but only far enough to get the eye beyond the neck of the bladder. Just as soon as the urine begins to flow, stop passing the catheter. Why? Because an irritable bladder resents anything like a foreign body. If you pass the catheter some distance into the bladder, pretty soon the urine flows out, the wall of the bladder will touch the catheter, and just as soon as it touches the foreign body it will flop right down the end of the catheter, bruising itself. It is a good plan to employ a catheter which has a hole directly at the end.

Medication by the Mouth.—Take it all in all, I think atropia is the best remedy. I prefer it to belladonna. I usually give it according to this formula :—

℞.	Atropiæ sulphatis,	gr. j
	Alcohol,	
	Aquæ, āā	fʒ ss. Solve.

Of this I give from four to six drops. Patients rarely take more than six drops without producing dryness of the throat and dazzling about the eyes. If you choose to add soda, sweet spirits of nitre or some diuretic, very well.

When it comes to injections into the bladder, I must confess that my own experience has not been very satisfactory. The proper plan is to inject with a double canula. Injections of the sulphate of morphia may be used in the strength of three or four grains to the fʒ . This is not curative. It simply obtunds the pain. Quinine (five grains dissolved in an ounce of water by the aid of dilute sulphuric acid) has a good reputation. Carbolic acid (two, three, four or five drops to the fʒ) has also been used.

For chronic cystitis, I know of nothing so good as strong solution of nitrate of silver, beginning with two grains to the ounce and increasing the strength every day by one or two grains until you reach twenty grains to the ounce. Such a solution cannot be left in the bladder very long. Do this: Inject the solution and then begin and count one—two—three—four—five—six—seven—eight—nine—ten ; ten seconds ; then withdraw the fluid. When you employ this injection you usually have to give a hypodermic of morphia, as the pain is very severe. I should, however, not adopt this treatment until after dilatation had been tried.

Periscope.

Ether vs. Chloroform.

Dr. T. Pridgin Teale, Surgeon to the General Infirmary at Leeds, thus writes, in the *British Medical Journal*: It is confessedly difficult, perhaps even impossible, to settle, by statistics, the question of the relative danger of these two anæsthetics ; chiefly for the reason that, while we know pretty nearly how many deaths from each agent occur during the year, we have not the means of ascertaining the relative proportions of the cases in which each anæsthetic has been used.

Such being the case, it may be worth while to record the opinions of those who, having for a great number of years had experience of chloroform, have also for many years (in my own case, more than six years), almost abandoned it in favor of ether. I wish, therefore, to tender my conclusions for what they are worth, based, as they are, upon what I have seen in the practice of my colleagues and myself at the Leeds Infirmary, and upon my experience of anæsthetics in my private practice. My conclusions are as follows :—

1. Ether, *properly administered*, is a much safer anæsthetic than chloroform. So much safer do I believe it to be, that I counsel every surgeon whom I can influence in the matter to study the method of its right administration, and to let ether take the place of chloroform. The exceptions I make in favor of chloroform are: in infants, in patients subject to asthma or chronic bronchitis, and also, perhaps, in cases of abdominal obstruction, with difficult breathing, in which an operation has to be performed.

2. When many operations have to be done in rapid succession, to use ether is a great economy

of time. A good "etherist" can get most patients under its influence in from one and a half to two minutes, whereas, in my experience, chloroform must be given from six to fifteen minutes before an operation can be commenced. I am aware that chloroformists trained in Edinburgh usually administer chloroform more rapidly than those trained in English hospitals.

3. A patient under the influence of ether is far more passive, and, therefore, in a more convenient condition for operation, than one under chloroform. As soon as the effect of chloroform is passing off, the patient becomes, as a rule, and often very suddenly, very sensitive to pain; whereas, in the case of ether, especially if the patient have been kept for some time under its influence, the return of sensibility to pain is very slow. In fact, a patient may become so far conscious as to converse with the surgeon while stitches are being placed in the wound, and at the same time be entirely unconscious of pain. This was not my experience of chloroform.

4. When ether is administered without food on the stomach, troublesome sickness is very rare.

5. In using ether, the safety and comfort of the patient, the rapidity of the anæsthesia, and the convenience of the surgeon in operating, depend very directly upon the method of administration employed, and the manner in which the administrator does his work.

6. There are good methods of administration of ether and bad methods, and there are good and bad "etherists." The varying opinions of the value of ether which prevail in the profession probably depend very directly upon the varying methods and manners of administration.

7. It is a bad method to give "ether on a towel," as first taught us by Dr. Joy Jeffreys, to whom England is deeply indebted for his successful crusade in favor of ether. This involves a great waste of ether, ten to twenty ounces being required. The patient's lungs are chilled, and bronchial *râles*, struggling, and maniacal excitement not unfrequently result. I, along with my colleagues, commenced ether under this system as a duty, and by no means an agreeable one, and held on doubtfully when I suspected that some patients probably died from the effects of the chilling of the lungs.

8. It is a bad method to give ether with the American basket-work frame, which, though not much better than the towel, served a good purpose as a step to better things.

9. The good methods are those in which the patient breathes over ether into an India-rubber bag, a method, I believe, introduced into practice by Dr. Ormsby, of Dublin, and carried to further perfection by Mr. Clover. In this method, the patient breathes the same air over and over again for six or eight times, thereby economizing the heat of the air-passages, economizing ether, and enhancing the effect of the ether by partial asphyxia. My experience of the use of Clover's smaller inhaler, under good management, is this: (*a*) A patient can generally be ready for operation in a minute and a half, sometimes in less than a minute; (*b*) There is rarely any struggling; (*c*) Noisy excitement hardly ever occurs—perhaps, in my private practice, once in a hundred times; (*d*) *Râles* in the trachea are but seldom heard; (*e*) Instead of six or eight ounces of ether being used in a short operation, and sixteen to twenty in one lasting an hour or an hour and a half, half an ounce or less suffices for a short operation (such as "sphincter-stretching" or "iridectomy"), and two to three ounces for an operation of an hour's duration, such as colotomy or excision of a joint.

10. The administration of ether by inferior methods is still too common, and was until recently prevalent in some of our larger hospitals.

11. Even with Ormsby's or Clover's inhalers, there is an infinite variety of skill in different etherists.

12. In order to become a good etherist, the administrator must *study how* to give ether, must watch the patient *attentively* while giving it, and during the earlier inhalations must very carefully and *studiously adjust* the anæsthetic to the sensations of the patient.

13. A careful, attentive student, with tact, and not hard and unfeeling, can easily and in a short time be taught to give ether properly.

Since the adoption of Clover's inhaler, I have had singular freedom from anxiety about my anæsthetics—far greater freedom than in the previous period, when I had to depend upon chloroform.

Finally, I would say that this favorable opinion of ether is based upon my experience of its use by a series of very able administrators—some in the Leeds Infirmary, others while acting as my private clinical assistants. Speaking as a looker-on, rather than as an administrator, I should say that the chief points in the right administration of ether are: first, to overcome the nervous dread of the patient by applying the mouthpiece only; then to turn on the ether gently, until the glottis become tolerant and the patient is slightly unconscious; lastly, to complete the anæsthesia rapidly. In advising beginners, I compare the regulation of the quantity of ether to the "curve of harmonic progression."

Addison's Disease.

In the Boston *Medical and Surgical Journal*, Dr. Hall Curtis reports the following case: The patient, aged 54, previously in good health, first began to complain about May 1st, 1881, of exhaustion after rising in the morning, and of difficulty in dressing himself, requiring frequent rests. For some little time before his appetite had been failing. From May 1st to July 1st he lost flesh rapidly. He became somewhat restless and nervous at night. The only prominent symptoms were loss of flesh and strength, and a peculiar color; once or twice looked very yellow. Urine was examined and found free from albumen; color normal; specific gravity 1.015; sediment slight; reaction acid; in fact, there was nothing abnormal about it. In July he went to the seashore, visiting the city but seldom. Took milk freely and all the most nourishing food. Appetite improved slightly, as did his color. On July 2d a consultation was held, and a most critical

examination made, without detecting any disease, although the possibility of Addison's disease was suggested by the discoloration of the face. The blood was examined microscopically, and found to vary but slightly from the normal standard. He was placed on the use of vinum cibi et ferri cum cinchona, and Fowler's solution; the latter, proving too irritating, was omitted. Massage was resorted to, and its influence was marked in improving the capillary circulation and restoring the perspiratory function of the skin, and, also, in reawakening the muscles, nerves, and spinal cord to their normal function. It was noted, on August 21, that during the past thirty-six hours he had been troubled with frequent dejections, thin and yellowish, no blood or mucus, and without much pain. The hands and feet were quite cold. The face was quite dark, almost a copper color, with many purpuric spots and points. On the forehead were large, irregular patches of color of a deeper brown. The eyes were sunken, conjunctivæ slightly congested, and with a tinge of yellow; under the eyes the pigment was nearly black. The deep color of face extended half way down the neck, gradually fading in depth of shade. The hands were quite dark, with spots and flecks of a deep chocolate color, ceasing abruptly just above wrists; the inside of the elbows showed a deposit of pigment, which was also very marked on the outer aspect of the joint.

Treatment consisted in a hot rectal douche three times a day, followed by starch and laudanum enema (fifteen drops to half an ounce), Hoffman's anodyne, one drachm three times a day, hot fomentations to abdomen, hot bottle to feet, claret, glass of milk, with two teaspoons of lime-water every two hours.

He now grew rapidly worse, and it is reported, on August 28, that yesterday he passed a quiet day, taking nourishment freely, requiring no sedative; now decidedly weaker; pulse 128; respiration 32 to 36; intellect duller; voice very faint; one dejection since yesterday A.M.; mouth half open; tip of tongue dry and glazed; passed urine freely this morning; temperature in axilla last evening 98 3° F. 7 P.M. Has been quiet, without complaint; delirium constant but quiet; temperature 99.3 F.; hands and arms abnormally warm; legs cold; pulse 130; respiration 40; eyes closed; pupils respond to light; does not reply to questions; has passed urine twice; unable to drink, or unwilling; fed with a spoon.

The night of the 28th was tranquil. Refusing food, he died, without a struggle, at 9.40 A.M., on the 29th.

Autopsy.—Left supra-renal body was not disorganized; altered in shape from the well-known cocked hat to an irregular, lobulated appearance, the largest lobule the size of a Lima bean. On section, yellowish gray, homogeneous surface, with caseation, here and there softening; the size of organ but slightly increased.

Right supra-renal body presented the same appearance, only more marked; the largest lobule, at top of gland, size of end of thumb.

The other organs were comparatively normal.

Narcotism in Infancy.

Dr. H. Cripps Lawrence says, in the *Practitioner*: Given a healthy child to start with certain results will follow the administration of narcotics, with an equally certain regularity.

1. In the early administration of a narcotic, more or less diversified, according to the temperament of the infant, a modified degree of excitement will supervene, to be followed by sleep; and this favorable condition of things may recur for a period varying from a few days to a week or two. If, however, the repetition of the narcotic be at all frequent, or if it be exhibited in any but a very small amount, this period of favorable narcosis will be proportionately diminished, and the chances of its lethal effect increased.

2. In some infants the effects of the narcotic will be to speedily constipate, for, as in the adult so in the infant, a narcotic lessens at once the secretions and movements of the stomach and intestines, and consequently digestion becomes arrested.

There is, however, a class of cases met with in infancy, wherein infants, the subject of imperfect digestion associated with colic, become for a time benefited by a moderate amount of narcotic. Here the sedative acts by checking peristalsis, and so enables the food to remain a longer time in contact with the digestive juices, and thus to become more perfectly digested. This condition, however, is more frequent in early childhood than in infancy.

A third and more frequent sign of the administration of a narcotic in the infant is the occurrence, sometimes the concurrence, of diarrhœa and vomiting. When these occur a longer time will elapse than when such conditions are absent, before profound narcosis ensues.

3. In addition to the above, diaphoresis and diuresis may occur, one or both. Either of these may and often will be present in an inverse proportion to the other. The predominance of either will be dependent upon the amount of fluid ingesta, the character of the fluids taken, and the condition of the temperature of the weather present at the time. Obviously, warm weather or an over-heated atmosphere will promote diaphoresis, while cold weather would augment diuresis.

4. The intestinal evacuations soon alter in character, becoming paler and more solid in consistency, diminished in their frequency, and increasingly more and more deficient in bile, accompanied by a change in color, from yellowish-green to verdant green, with or without mucus, and if very constipated, accompanied by streaks of blood, owing to the tenesmus which is associated with the expulsion of the hardened, ill-digested fæces.

5. Another vital symptom, though of later occurrence than the preceding, is marked depression of the vital powers, evidenced by sinking of the anterior fontanelle. This is accompanied by other signs of want of vitality, viz., feebleness of pulse, loss of weight, an earthy complexion, wasting, especially marked in the pinched and anxious expression of the face. By this time the infant alternates between efforts at peevish whimpering and imperfect somnolency.

The pupils will be found, in the earlier stages of narcotism in infancy, to be frequently contracted, but when the stage of fontanelle depression is reached they may contract or dilate, and one pupil may be larger than the other. This condition I believe to be dependent upon variations in the amount of fluid present in the ventricles of the brain.

So soon as this stage is reached, any subsequent dose of a narcotic may prove speedily lethal, and the greatest care and caution become necessary to avert an untoward result. It is at this point that I believe the cumulative effect and action of the narcotic assumes a point of much peril to the infant. One of two results may now supervene: either clonic convulsions may set in, though these are not very frequent, or, and much more commonly, profound and perhaps fatal coma.

Malignant Pustule.

Before the Royal Medical and Chirurgical Society (*Medical Times and Gazette*), Dr. J. N. C. Davies-Colley read notes of two cases of malignant pustule, with a table of seventeen cases which had been treated at Guy's Hospital; together with a report of the microscopical examination of sections from the skin of the cheek affected with charbon, by Dr. F. Charlewood Turner. In this paper Dr. Davies-Colley has tabulated seventeen cases of malignant pustule or charbon which have occurred during the last nine years at Guy's Hospital, and he has given more fully the details of two which were admitted into his wards last year.

Case 1.—F. R., aged 31, worked in a hide warehouse, and had been engaged for eight days with Australian fleeces. On April 10, 1881, a small red spot appeared on his right lower eyelid. It grew rapidly. On the 16th he was admitted, with the eye closed, and with a partly dry, partly vesicular, eschar covering nearly the whole of the swollen lower eyelid. He was in little pain, but weak, trembling and feverish. The glands were swollen. Immediate relief followed the excision of the eschar. In a few weeks the wound had healed, but the eyelid remained everted. Bacilli were found in the blood at the time of the operation.

Case 2.—T. W., aged 39, a tanner, had been handling foreign hides until July 2, 1881. He then left off work, and on July 6th noticed a red itching swelling on the cheek. It grew rapidly. On the 10th loss of appetite; and on the 11th he was admitted with a raised, nearly circular patch, of more than one inch in diameter, in the middle of his cheek. The centre of this patch was slightly depressed, dry and nearly black. The sides were covered with small, closely packed vesicles. There was swelling of the cervical glands and œdema of the neck. The eschar was excised, and chloride of zinc applied. He recovered rapidly. A colored drawing of the charbon, and drawings of the microscopic sections of the eschar, showing the bacilli anthracis in the corium and around the hair follicles, were shown.

The author wished to call attention to the following facts: 1. Malignant pustule or charbon is not infrequent among tanners and wharf laborers who have to handle foreign hides and fleeces. 2. It has not yet been observed at Guy's Hospital as a primary disease in the viscera, or in the form of malignant œdema of the integument. 3. It has been seen only on exposed parts of the body—*e. g.*, the face, the neck and arms—the most dangerous position being the neck, probably from its vicinity to the larynx. 4. The seventeen cases were between the ages of eleven and forty-seven, and the majority were young adults of the male sex. 5. Twelve out of seventeen cases occurred in September and the four following months. 6. The disease may be confounded with malignant facial carbuncle, poisoned wounds, and primary chancres of the face. The chief points to notice are the painless character of the eschar, its vesicular margin, and slightly depressed, dry, blackish centre. 7. The nature of the disease is not unfrequently overlooked, and its symptoms have been attributed to such causes as the bite of a mosquito, or the absorption of arsenic through an abrasion. 8. It should be treated at once by excision or free cauterization. Out of fifteen cases in which the eschar was excised, eight were already suffering from constitutional symptoms, and twelve had considerable œdema or glandular enlargement, yet all recovered. The two cases in which excision was not performed were admitted with dyspnœa and other serious symptoms, and it is probable that in them the operation would not have averted the fatal result. 1. Swelling up of the most superficial part of the cutis, with the formation of a ring of papules surrounding a zone of vesicles, at the centre of which is an eschar, is the earliest change recognizable. 2. That bacilli are present in their papules, but not beyond them, being 3. Numerous in the tissue of the cutis immediately below the eschar, and above to its borders, and most abundant just below the Malpighian layer of the epidermis covering the outer part of the eschar.

The President said he thought the case of the gentleman referred to had come under his notice, and he did not consider it a case of charbon. The gentleman had been at the Oxford and Cambridge boat-race on a very hot day, and was bitten under the chin by a fly. He died very soon, of acute septicæmia. The bite had been either poisonous from the first or had been poisoned by scratching from matter under the nails.

Mr. Bryant was sure the disease was not sufficiently recognized, and he ventured to suggest that the very case mentioned by the President was an instance in point. The central, black eschar and indurated and reddened base could hardly be mistaken, and early recognition was of the utmost importance, as immediate operation was necessary, even in doubtful cases, especially where the charbon was situated on loose connective tissue. In his own case, though soon operated on, the œdema spread to the glottis and killed the patient.

A Two-Headed Monstrosity.

Dr. Milner Moore records the following rare and interesting case in the *Lancet*:—

On March 25th I was sent for to see Mrs. A. B., aged thirty-one, who had had labor pains for

more than ten hours, increasing gradually in severity and frequency. She had borne two full-sized children previously, by natural means, the last being two and a half years old. Liquor amnii had escaped at 7 A.M., March 24th, but no pains occurred until midnight, when they set in with regularity. When I saw her at 10 A.M., March 25th the os uteri was only partially dilated, very high up, and the occiput presented anteriorly; pains occurred with severity every five minutes. I watched the case anxiously until 5 P.M., when but little progress in the passage of the head had occurred, but the os uteri was more dilated, pains were strong and frequent, but ineffectual, and all the signs of weariness were coming on. I applied the forceps with some difficulty, owing to the partial dilatation, administered chloroform, and proceeded to use traction, which after some minutes brought the head well down on the perineum and partially through the vaginal outlet. I could not succeed in delivering the head, and at the cessation of traction it receded completely. Examining then once more, and passing my fingers beyond the head, I found what I considered to be the vertex of a twin which seemed to prevent the passage of the body belonging to the first head. At this juncture I sent for my partner, Dr. Dewes, who speedily came. I put the patient completely under chloroform. Dr. Dewes reapplied the forceps, and succeeded in delivering the head, but it receded as soon as released from the blades. Dr. Dewes agreeing with me, after another examination, which revealed an ear high up beyond the promontory of the sacrum, that we had to deal with a monstrosity, decapitation was decided upon, and carried out with some difficulty. As soon as this was done, I could feel a shoulder above the pubis, and a neck and head above the promontory; then, with the concurrence of Dr. Dewes, I passed my hand, seized a foot, and turning the child, delivered with comparative ease.

The monster proved to be a large female child, with two heads and necks, one trunk, and two upper and lower extremities. The circumference of its chest at axilla, was 15½ inches, length 19½ inches, and weight 8¾ lbs. The right head presented with occiput anteriorly, and in the second position. On dissection, the following were the positions of the viscera: The sternum was to the left of the body, but the complex heart, which lay behind it, was directly in the centre. The heart consisted of one auricle, from which projected, vertically downward, two distinct cone-shaped pairs of ventricles, those on the left lying one in front of the other, while those on the right lay side by side. From the anterior, thicker ventricle on the left side there proceeded a large vessel which first gave off the pulmonary artery, and then formed a communication with another vessel, which arose from the posterior thinner ventricle, and gave off two branches to the upper limb, and head and neck; by the joining of these vessels, a large trunk was formed, which met a similar artery from the right side, and formed the descending aorta. On the right side a large vessel originated from the thick outer ventricle, gave two branches to the upper extremity and neck, and a communicating branch to the smaller artery, proceeding from the inner thin ventricle, which then went to the lungs; the vessel formed by this junction met its counterpart of the left side two inches from its origin. There was a complete set of lungs on each side of the thorax—that is, two lungs with three lobes in each. The other organs were as in a single child. The spinal column consisted of two spines, having origin from one sacrum, blended together as far as the third dorsal vertebra, where they separated, and rudimentary ribs appeared to be starting from the inner side of the right spine.

The patient made a good recovery.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Two cases of hemi-achromatopsia are carefully reported by Dr. Henry D. Noyes, in a reprint from the *Archives of Ophthalmology*.

——Biology is studied with much zeal in the Johns Hopkins University. Those who would like to see the course laid out for the coming year should write for the *University Circular* in this department.

——The Proceedings of the Alumnæ Association of the Woman's Medical College of Pennsylvania form a pamphlet of 42 pages. The numerous letters read from absent alumnæ represent most of them as well satisfied and in successful practice. Perhaps the dissatisfied did not care to write. Several original articles are added, some of which are reprinted from periodicals. It is evident that females as physicians are acceptable to the community, and have now a firm foothold.

——The contents of *Lippincott's Magazine* for August are light and summery throughout, suggestive of mountain rambles and seaside excursions. "St. Jerome's Day with the Pueblo Indians" is a well illustrated paper descriptive of a half-religious, half-barbaric festival in New Mexico. An "Adirondack Home," by P. Deming, has the well known characteristics of the writer's Atlantic sketches, close observation, quiet humor, and sympathetic treatment of the primitive freshness and quaint features of life in the wilderness. "The Romance of Childhood," by Henry A. Beers, is a charming paper, tinged with a delicate fancy, by turns tender and playful. Mrs. M. G. Van Rensselaer's concluding paper on the Alleghanies gives a deeply interesting sketch of the career of Gallitzin, the prince missionary, who did so much for the early civilization of the mountain regions of Pennsylvania, and, in contrast to this, a description of the Cam-

bria Iron Works, which form the most striking features of the actual life of that district. "Bay Beauties and Bay Breezes," by P. V. Huyssoon, is very amusing, and the other articles are all attractive.

BOOK NOTICES.

How We Ought to Live; a Practical Guide for the Preservation of Health and the Attainment of Longevity. By Joseph F. Edwards, A.M., M.D., etc. Philada.: H. C. Watts Co., 1882. 8 vo, pp. 636.

As time progresses it grows more and more evident that the noblest, the most useful arena for the physician's labor is in the *prevention* of disease. Hence the enormous impetus which of late years has been given to hygiene.

We welcome the volume whose title is given above as a valuable auxiliary in the crusade against those powers which, to use an expression of Matthew Arnold's, make for disease, unhappiness, and the deterioration of the race.

The author has a love for his subject; he has thoroughly mastered its details; he presents them as they are understood by the masters of science; his style is remarkably lucid and attractive, and his work, therefore, one that cannot fail to produce widespread and excellent results. There is in it no hobby-riding, and it is marked by a happy avoidance of that technical language which is so repelling to the general reader. The book may be characterized as a series of agreeably written short essays on almost every topic which touches upon hygiene.

In a general way the sequence of these essays follows that of the life of the individual. The earlier ones are on the care of infants, the care of children at home, and of children at school. To these follow others addressed to adults, on such subjects as the hygiene of building, ventilation, work, eating, exercise, bathing, sleep, dress, and so forth. The objections to the use of tobacco and alcoholic beverages are stated fairly and fully. Special chapters are added for the guidance of persons liable to consumption and heart disease, and the hygienic rules particularly applicable to pregnancy, nursing and advanced age are accurately set forth. The Appendix contains a number of letters from men of very advanced years, giving their history, so far as it throws light upon the rules of attaining old age. These are very interesting, and cannot fail to command the attention of all who take up the book.

In all respects the volume is one which we can heartily commend to the public, and which merits extensive popularity. Were it introduced into every family and read diligently, the misery and mortality of the land would both be greatly diminished.

Syphilis. By V. Cornil, Professor in the Faculty of Medicine of Paris. Translated, with Notes and Additions, by J. Henry C. Simes, M.D., and J. Wm. White, M.D. Philadelphia: Henry C. Lea's Son & Co. 1882. pp. 461.

The main questions regarding syphilis are treated of as mostly settled in this work. The author considers the dualism of the chancres as completely established, and proceeds upon this theory. Some of his statements excite surprise, as when (page 33) he says the ordinary period between exposure and the appearance of the infecting chancre is "twenty-five days, frequently six weeks or two months," which seems also to have staggered his translators, for on a later page (98) they say "very rarely six to eight weeks." On such an important point, such contradiction does not impress one favorably.

It is conceded that in "a few" cases true indurated chancre is *not* followed by syphilis, even if left without treatment; and it is also conceded (page 99) that simple venereal ulcer is sometimes followed by the systemic disease. If this is so, the duality is far from established.

The local treatment of true chancre is not considered of much importance. Excision may be of benefit, but caustics are disapproved. The translators believe that excision, in certain cases, prevents the development of the disease.

These practical points have taken our attention from the chief merit of the book. This is as a treatise on the pathological histology of syphilis. It is with the special purpose of showing the evolution of the disease as indicated by histological changes that the author prepared his volume. In this respect it is much superior to any other we could name, and merits the close reading of syphilologists. A syphilitic ulcer appears to be a new cell growth, and to offer peculiarities which separate it from other forms of tissue destruction. These are amply shown by both description and illustration.

The translation is very well done, and the reader will not regret the considerable additions which the translators have inserted in the text, drawing from their own experience and reading. They do not always agree with Prof. Cornil, nor should we ask them to. The volume is a welcome contribution to syphilology.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

LEGISLATION FOR THE PREVENTION OF SYPHILIS.

The more carefully the insidious and deteriorating effects of syphilis are studied, the clearer does it become that the welfare of humanity demands that steps should be taken to prevent its extension. The prejudices of bigots must be disregarded, and the fear of unpopularity must be set aside by the profession in this matter, if its members intend to do their plain duty.

The earnest efforts of a few enlightened men are at last beginning to bear fruit. At the Eighth Annual Meeting of the American Public Health Association, in December, 1880, at New Orleans, the following resolution was offered by Dr. McCormack, of Kentucky, and adopted by the Association:—

Resolved, That for the purpose of securing uniformity in legislation in the States of this Union, for the prevention of venereal disease, the Committee on Prevention of Venereal Disease be reconstituted and instructed to prepare drafts of a State law and of a municipal ordinance calculated to secure the desired results, and report at the next annual meeting of the Association.

In compliance with this, Dr. John Morris, of Baltimore, submitted the draft of an act to the Association, at its meeting in Savannah, last December, which was referred to the committee, with instructions to make a final report at the Tenth Annual Meeting, which will take place in Indianapolis next October.

We give below the outline of the act, and the committee will be pleased to receive any suggestions as to amendments in its form. They should be sent to Dr. Morris at as early a date as practicable:—

An Act, entitled "An Act to prevent the spread of Contagious Diseases."

ARTICLE I. *Be it enacted by the* [Senate and House of Representatives of the State of.....
.....],

That any person within the jurisdiction of the State [or Territory], who shall knowingly communicate, or be instrumental in communicating, directly or indirectly, any contagious disease, such as smallpox, scarlet fever or venereal disease, shall be guilty of a misdemeanor, and subject upon conviction in any court having cognizance of misdemeanor [where the offence may have been committed] [in the State or Territory], to the punishment of six months' imprisonment in the [County Jail].

ART. II. That if any person being the owner, agent or occupant of any house, room or place within the jurisdiction of this State [or Territory], shall have reasonable cause to believe any person located permanently or temporarily therein to be affected with a contagious disease; and shall fail to make such fact known to the proper health authorities [or if there be no such officials, to the nearest magistrate having jurisdiction of misdemeanor], he or she shall be deemed guilty of a misdemeanor, and upon conviction in any court having jurisdiction of misdemeanors [where the offender may reside or the offence have been committed], shall be liable to a penalty not exceeding [five hundred] dollars or to imprisonment not exceeding six months, or to both.

ART. III. That the State Board of Health, with the approval of the Governor, and the Health Board of the City of.....with the approval of the Mayor of said City, shall have power to institute and carry out all suitable measures to prevent the spread of diseases of a contagious character, and may, if deemed advisable, remove to proper hospitals selected by them all persons suffering from contagious diseases, who, neglecting proper precautions, imperil the health of the community.

ART. IV. That this Act shall go into effect from and after the.....day of
.....A. D.....

It will be seen that all police regulations, medical inspections and special rules for controlling houses of ill-fame are left for local legislation. This is as it should be, for no one system would suit all cases.

Nor does the act definitively lay down the misdemeanor it contemplates so specifically but that considerable latitude is left to its interpretation. It must remain for the courts to decide what constitutes "reasonable cause." It is plain that no brothel-keeper will denounce an inmate of her own house. The "reasonable cause of belief" must be the statement of a physician occupying an official position, and without this the act will in those cases be of no avail.

If any further evidence were wanted to show the imperative necessity of such an act, it is presented in a paper read before the New York Medico-Legal Society last April, by Dr. Albert L. Gihon, Medical Director U. S. Navy, on "The Prevention of Venereal Diseases by Legislation." A copy of this can be obtained from the author, 1736 I street, Washington, and it should be read by all whose minds are not clear as to the propriety of such legislative action. It presents, in telling language, the ravages of the disease and the cause there is for its prevention whenever this can possibly be effected.

CHLOROFORM INHALATION.

Notwithstanding the many fatal accidents caused by chloroform narcosis, and notwithstanding the many substitutes—ether at their head—recommended and employed, like chloroform, to produce complete insensibility, there are so many points in favor of the latter drug that we cannot be surprised at the many researches which have been instituted, either to detect the real cause of death by this substance, and the circumstances tending to favor and those which possibly may prevent a fatal result, or to find means by which the danger may be lessened, or at least the prognosis be based upon more definite knowledge.

There is no remedy which is so little disagreeable to animated beings and which so rapidly induces complete anæsthesia, as chloroform. We now know that the latter becomes especially dangerous in cases of organic lesions of the heart and of the lungs, and that its inhalation is very apt to be fatal in cases of advanced diffused kidney affections. But then cases have occasionally been met with where it seemed impossible to give any scientific reason for the sudden death, where anæmia of the brain could alone be said to have caused the fatal result. Careful investigations have of late more and more substantiated the fact that such accidents may be avoided, if the chloroform has been recently prepared, not been exposed to the light, and if a small quantity of alcohol (spec. grav. 0.834) be added to the chloroform. Dr. THEO. CLEMENS, who in 1850* made this question the subject of a thorough investigation, had again, some months ago,† the opportunity to carefully search for the cause of the intoxicating effects of inhalation of chloroform. The latter had been pronounced pure by a chemist, but CLEMENS found the same "self-decomposition" of the drug he had frequently noticed under similar circumstances. HAGER,‡ one of the most reliable of modern chemists, says that chloroform of the spec. grav. of 1.495–1.496 carries in itself all the conditions for a self-decomposition which may act very dangerously on the system. He says, in the work quoted, page 864, "Chloroform in the act of self-decomposition must be considered a very dangerous anæsthetic, and this the more, as the decomposition at the time of evaporation of the chloroform becomes far more active, and the physician should prefer, therefore, the so-called chloral-chloroform. But with a chloroform of a spec. grav. of 1.488–1.492 no such danger is to be apprehended."

CLEMENS has clearly proven, however, that by the addition of a little *spiritus vini*, chloroform, even after having been kept for years, will undergo no such self-decomposition. Chloroform containing five per cent. of alcohol will also not be altered by light. CLEMENS directed the treatment by chloroform inhalations of forty-eight cases of grave pneumonia, losing only two cases and employing the drug in the form indicated. Chloroform to which alcohol has been added does not lose any of its narcotic influence, becomes, when

* Deutsche Clinic, Dec. 21st, 1850.
† Medicin Central Zeitung, LX, 1.
‡ Handbuch der pharmaceut. Praxis, etc., Berlin, 1876.

inhaled, more agreeable to the taste, and can be taken by persons unable to inhale pure chloroform.

The importance of this fact will be appreciated if we remember that a number of cases of grave pneumonia with severe orthopnœa have recently been reported by German authorities as cured by the inhalation of chloroform with alcohol, and that the latter method (inhalation of alcohol) has been found to be of greatest benefit in asthenic forms of febrile disorders.

ASCITES IN CHILDREN.

Ascites in children is a rare disease. If it happens, it is generally produced either by tubercular peritonitis or by cancer of some of the abdominal organs. Dr. Seiler, in Dresden, contends (*Berl. Klin. Wochenschr.*, xviii, 26, p. 365) that whenever the causes just mentioned cannot be detected in ascites of children, a diffused syphilitic hepatitis or circumscribed gummata will *always* be found to have given rise to the abdominal dropsy. He thinks that the cases so far reported belong to the category of retarded hereditary syphilis, and that this form of ascites always yields to mercury or iodine, or to a combination of both. At the same time he admits that occasionally this ascites may be caused by a curable, simple hypertrophic cirrhosis of the liver. For better explanation, Seiler gives the history of four cases:—

1. A girl, aged 13, after having frequently complained of not feeling well, without the appearance of any specific signs or symptoms, was taken sick, February of last year, with swelling of the abdomen, which on examination was found to be distended with a rather large quantity of free fluid. June 11th, about five quarts of a serous, light yellow fluid, containing a considerable percentage of albumen, was withdrawn, by paracentesis, from the abdominal cavity, after which operation the liver could be felt as a soft tumor extending down below as far as the middle of the abdomen. Mercurial inunctions into the abdominal walls, and internal administration of iodide of potash, caused a diminution in the size of the liver, and the ascites did not reappear. Cure within six weeks.

2. A four-year-old girl, with really enormous ascites; otherwise perfectly healthy. By paracentesis, four quarts of turbid serum was withdrawn, when it was found that the liver reached as far as the crista ilei. Seven weeks later tapping had again to be resorted to, but this time the quantity of the fluid was less. The same treatment as in the first case was continued for two months, when a tonic treatment was instituted. When, eight months after its admission, the child was discharged from the hospital, the ascites had disappeared, but the liver was still a little lower down than the middle of the abdomen. Seiler saw the girl again when she was thirteen years old, and on percussion, found the size of the liver to be normal. The ascites had never returned.

The third and fourth cases concern a seven and a fifteen-year-old girl, and contain nothing of special interest, their history being similar to the first two cases.

That there may be still other causes producing ascites in children there can be no doubt; the writer of this saw one in which, in consequence of intense inflammation of the portal vein (due to a cold?) and occlusion of the same near its entrance into the liver, the most intense ascites developed itself in a boy nine years old. The case ended fatally. Kormann has also reported another case (*Jahrb. f. Khkde*, xvi, p. 170, 1880) in which the etiology did not coincide with that given by Seiler.

Notes and Comments.

Rupture of the Uterus.

A great deal has been written about the etiology of rupture of the uterus, and the following case, which we find reported in *Schmidt's Jahrbücher* (1882 No. 1) is especially interesting, as no plausible cause could be detected. A laborer's wife, aged thirty-five, and mother of seven children, had again become enceinte. The first eight months the case progressed favorably. At the beginning of the ninth month she became slightly feverish, and continued so for several days, when

she experienced labor pains and went to bed. Soon afterward she was seized with a most violent pain in the abdomen, which was followed by a slight hemorrhage from the vagina. The woman then fainted. A physician was called and he applied a tampon of cotton wadding.

In the afternoon of the same day the patient was seen by Dr. M. Hofmeier, of Berlin. He found her in a state of collapse, throwing herself restlessly about in the bed and crying out with pain. To all appearances the case was one of septic peritonitis. The patient was chloroformed, and parts of the fœtus now became visible through the thin abdominal walls. Dr. Hofmeier opened the bag of waters and extracted the child easily, by the feet, after turning. There was no difficulty in removing the placenta by traction on the cord. Further examination revealed the fact that the uterus was ruptured on its right side, from the fundus down to near the external os, so that the head penetrated, without obstacle, into the abdominal cavity. The latter was filled with fluid and coagulated blood. The patient was brought into the hospital and laparotomy performed. The wound was closed by twenty sutures. On the second day after the operation the patient died. The pelvis was normal, and the contractions of the uterus had evidently been of a mild character only. The rupture was 14 centimeters in length. The fœtus was in the beginning of the ninth month.

It may be supposed that the rupture took place at the moment the patient experienced the sudden pain; the fœtus had occluded the os, and so the hemorrhage took place into the abdominal cavity. The walls of the uterus were thick and appeared in a perfectly healthy condition. Of fatty degeneration, which was observed in Simpson's case, not a trace could be found. None of all the causes which Bandl mentions as producing rupture of the uterus were present in this case.

Administration of Tannic Acid.

The influence of tannic acid on albuminuria cannot be denied. Even if we should not be able to prevent the progress of the disease to its fatal end, by reducing the quantity of albumen in the urine, or by totally removing it, we stop, at least, a drain of the system, and may thus be able to prolong life by causing a cessation in the waste of albuminoid compounds. Of late, Dr. H. Ribbert, in Bonn, has made some very important researches (*Cbl. f. d. Med. Wissensch*, 3, 1882) in this direction. He contends that we can undoubtedly reduce the amount of albumen excreted, and that our efforts will be crowned the more with success, the earlier in the disease the regular internal administration of tannic acid is commenced. He recommends large doses of the sodium tannicum.

In connection with this, Dr. Lewin (*Deutsche Med. Wochensch.*, 6, 1881, has made some experiments to prevent the disagreeable effect of preparations of tannic acid on the mucous membrane of the alimentary canal. For this purpose he recommends the following prescriptions:—

I. SODIUM TANNICUM.

℞. Solut. acidi tannici, gr. xvi–xxc : f℥ v
Adde.,
Solut. sodii bicarb. q.s. ad react. alkalin.

SIG.—To be kept in a well-corked glass, and used within one or two days.

II. TANNICUM ALBUMINATUM.

℞. Solut. acidi tannici, ʒ ss : f℥ iij
Adde, agitando,
Solut. albumin. ovi unius., f℥ iij.

SIG.—The greater the quantity of the tannic acid, the greater must be, in proportion, the amount of the white of the egg.

III. TANNIC. ALBUMINAT. ALKAL.

℞. Acid. tannic., ʒ ss–gr. lxxv
Aquæ destillat., f℥ iij
Adde agitando,
Albumin. ovi unius,
Sodii bicarb. solut. q.s. ad solut. limpida.

SIG.—Best adapted for a longer course of tannic acid.

Sugar in any form should be avoided in these preparations.

Tumor of the Brain with Decided Eye Symptoms.

Dr. James A. Spalding had for a number of years a very interesting case of tumor of the brain under observation, and we find the case reported in *Schmidt's Jahrb.*, 1882, No. 1, pp. 50, 51.

An otherwise apparently healthy man, æt. 20, was attacked by the following symptoms in the order mentioned: *left*-sided paralysis of the abducens, continuing for ten days and apparently caused by exposure to cold while sleighing. Six months later complete paralysis of all muscles provided by the motor oculi of the *right* side set in. No improvement, but instead, after two more months, intense headache made its appearance, and continued daily for several hours. A year and a half after the initial symptoms vision was suddenly extinguished on the *left* side. At the same time paresis of accommodation and swelling of the optic nerve, with atrophy, developed themselves. About six months later the patient had an attack of severe vertigo, followed immediately by paralysis of the left arm, to which

gradually total left-sided hemiplegia was added, as well as facial palsy of the same side. The periodical pains in the head ceased entirely. The right eye also then became blind, while hearing was impaired. Death did not take place till five years after beginning of the first symptoms.

Post-mortem.—In the left anterior fossa was found a dense tumor consisting of two lobes, and reaching from the processus clinoideus anterior to the foramen magnum and sideways to the os petrosum. A second tumor of the size of a walnut was detected under the anterior lower surface of the left hemisphere of the cerebrum. The microscopical appearance of the tumors is not mentioned. Optic nerve, chiasm and olfactory nerves were found to be atrophied.

Styptic in Phthisical Hemorrhages.

Jaccoud (*Hémoptysie apyrétique chez les tuberculeux. Mon. de la Policlinique*, 3, 1882) recommends the following in cases of hemorrhages in tubercular phthisis:—

℞.	Ergotin,		gr. xvj
	Glycerin,		
	Aquæ destillat,	āā	℥j
	Aquæ laurocerasi,		℥ss. M.

A hypodermic syringe is filled with this solution, and, according to the severity of the case, from two to four such injections are made daily.

Clinical Thermometers.

The Second Annual Report of the Astronomer at Yale College states that the improvement in the manufacture of clinical thermometers in this country continues, and the thermometers he receives which are most misleading in their indications are those which come in from private practice, and which have been in use for a year or more.

These errors sometimes amount to 2°, which would render a clinical thermometer much more than worthless. He adds:—

"We have been much encouraged in this department of the observatory work by the cordial endorsement given to it by the medical press. There have been some suggestions made by gentlemen eminent in the medical profession, both privately and in print, concerning some new facts we should give in the certificates accompanying thermometers sent from here. The most important is contained in Dr. E R. Squibb's interesting paper on clinical thermometers, read at the New York State Medical Association's meeting at Albany and refers to the testing of thermometers for sensitiveness. He notes the difference in time required for different thermometers to attain their maximum reading, owing to the varying thickness and shape of the glass in the bulb, and suggests some test be applied which shall give the observer the time required for each instrument to reach its maximum. We have considered this matter, but so far have not devised a simple test which sufficiently approximates the conditions met with in medical practice to be of service in this connection."

Introduction of Aliments and Medicines Through the Nasal Cavity.

Fernet and Martel (*Schmidt's Jahrb.* 1882, No. 1, p. 63) have made a number of experiments to demonstrate the possibility of introducing aliments and medicines through the nostrils.

For this purpose the patient is placed on his back, in the recumbent position, while the head and the upper part of the throat are permitted to fall somewhat backward. The gum hose of a common nursing bottle is then pushed into the posterior part of one nostril, and the fluid—either containing nutritive substances or medicine—slowly poured in. In consequence of the peculiar position of the body, the floor of the nasal cavity and the velum form an oblique plane, so that the fluid mentioned flows directly into the pharynx and induces swallowing. Generally, and especially if the fluid is poured in slowly, the expected result ensues with certainty, and in a manner by no means disagreeable to the patient; only when the fluid is poured in too rapidly, a few drops may find their way into the larynx, causing the well known irritating cough.

Fernet and Martel have employed this method successfully in persons in a comatose condition, in children suffering from tubercular meningitis, and even in newborn infants too weak to take the breast or the bottle. This method may also be successful to introduce such medicines into the stomach which, in consequence of their bitter or nauseous taste, are rejected by the patient.

Créquy recommends, for this purpose, the introduction of a flexible gum tube (catheter). If this is pushed behind the velum, the possible reflow of the fluid, by the other nostril would effectually be prevented.

Martel reports two cases: one, where, in consequence of a fall on the head, severe concussion of the brain, with trismus and utter inability to swallow, set in, and the other, a case of pneumonia in a drunkard, the patient being totally unconscious. Here the medicines—calomel and

jalap in the first, musk and digitalis, in the second case—were successfully carried into the system by the method described, and though in consequence of their severity the cases ended fatally, the procedure itself achieved its object.

Vaginal Hemorrhage in a Newborn Child.

Dr. Josef Pollak, in Devecser, reports an interesting case in the *Wien. Med. Presse*, xxi, 27 p. 876. He observed in a female infant, four days old, a not inconsiderable hemorrhage from the vagina. The bleeding reappeared several times daily; after the third day the discharge assumed a reddish-brown, and later a chocolate color, and ceased totally when the infant was nine days old. At the same time there was noticed a swelling of the mammæ, and on pressure a milk-like fluid oozed from them, drop by drop. The latter symptom is rather common, while hemorrhage from the vagina in infants is exceedingly rare, but seems to possess much less significance than intestinal hemorrhage. The general health of the case just reported did not apparently suffer at all in consequence of the bleeding.

Ligature of the Innominate Artery.

It is reported, in the *Medical Times and Gazette*, that Mr. William Thomson tied the innominate artery of a man aged fifty years, the subject of subclavian aneurism. Mr. Barwell's ligature was used to secure the vessel. Up to the present time the patient is making satisfactory progress. The patient suffered from an aneurism springing from the third and second stages of the subclavian artery. Some months ago he refused to submit to any operation, and left the hospital. He, however, lately returned, the aneurism having increased in size, and then measuring three and a half inches in diameter at its base. Operation was again proposed, and was consented to; but pulsation ceased suddenly. This continued for twelve hours. During a week there were occasionally short cessations, but the tumor meanwhile enlarged, the skin became red, and it was determined to operate. The wound has entirely healed, with the exception of the opening left by the drainage tube; the pulse is 98, and temperature is normal; the tumor is smaller, absolutely still, and sensation is returning in the right arm, which had long been paralyzed by the pressure of the aneurism on the brachial plexus. Much interest is naturally felt in the result of this operation, seeing that of fifteen recorded cases only one recovered, the patient being a negro, operated upon by Smith, of New Orleans. In that instance there was severe secondary hemorrhage, and it became necessary to ligature the vertebral and internal mammary arteries.

Special Reports.

No. VIII.—Venereal Diseases.

Syphilis vs. Cancer.

The differential diagnosis between syphilis and cancer is oftentimes attended with much difficulty. In the *British Medical Journal* Dr. Thomas Drapes relates a case that well demonstrates the embarrassment with which the surgeon will be sometimes surrounded when endeavoring to differentiate between these two morbid conditions. The patient was a respectable married woman, aged 50. She began suffering from her throat, the first symptoms being pricking pains running through both sides of the throat. She experienced steadily increasing pain and difficulty in swallowing, so that only liquids could be consumed, and they would have to be held in the mouth and allowed to descend into the stomach drop by drop. She lost flesh and strength and was confined to bed. On entering the room one was immediately struck by the extraordinary fetor emanating from the patient, which possessed that peculiar pungent, stinking quality, so characteristic of cancer in its later stages. The back of the pharynx was thickly covered with purulent secretion. On examination with the finger a rugged, irregular mass was felt, occupying the back and right side of the pharynx; the surface was knobbed, hard and bossy. The age of the patient, the circumstances and the peculiar fetor indicated cancer, and a gloomy prognosis was made. Palliative treatment with iron was adopted, without benefit. Subsequently it was accidentally discovered that the patient had been treated two years before for a rash over her entire body, which went away after using medicine that she said "rotted her teeth." It also transpired that her husband had been treated for syphilis about a year before. Mercurial inunction was prescribed, and in a few days, along with it, three grain doses of iodide of potassium thrice daily. Immediate improvement commenced; in a week she could eat meat. The fetor and discharge rapidly and permanently disappeared; the gummatous infiltration steadily diminished, and perfect cure resulted.

Syphilitic Pachymeningitis of Cerebellar Fossa.

Before the Medical Society of London (*Lancet*)

Dr. Broadbent related the post-mortem appearances in a case of paralysis of the right seventh, eighth and ninth nerves. There was a syphilitic history; after pain in the right occipital region, paralysis came on successively in the seventh, eighth and ninth nerves of this side. There was deafness, as well as facial paralysis; paralysis of the sterno-mastoid and trapezius muscles, with atrophy so complete, that these muscles had practically disappeared. There was also paralysis of the vocal cord. Paralysis and atrophy of the right half of the tongue came on while the patient was under observation. It turned out to be a case of syphilitic pachymeningitis of the right cerebellar fossa. When the tentorium was divided the right lobe of the cerebellum was found to be closely adherent to the dura mater, and the thickened membrane to have strangled the nerves at their exit by the foramina. This was the sole lesion, the medulla and fons being quite normal, as were all parts of the brain. Dr. Hughlings Jackson said that in most of these cases there is a history of syphilitic disease, although not in all; in one case where there was but little doubt of syphilitic disease during life, after death a cyst in the cerebellum was discovered, while in another case was found a glioma, involving the medulla and pons.

CRANIAL OSTEOPHYTES.

Before the same society, Dr. Radcliffe Crocker presented a case of congenital syphilitic osseous thickenings and enlarged spleen, in a male infant eleven months old. The patient was a seven months' child. The skin is sallow and waxy looking, but he is well nourished. There are symmetrical osseous thickenings on each frontal bone, about an inch and a half in diameter, commencing about an inch above the orbits, which are separated by a sulcus of the breadth of the finger. The anterior boundaries of the fontanelles are thick, but the posterior thinner than normal. There is no cranio-tabes. The spleen is much enlarged, extending two inches and a half below the ribs and measuring three inches across. Dr. Sansom pointed out that in the rachitic skull the margins of the fontanelles were shelving, and not thickened nodular prominences, as in syphilis.

SYPHILITIC PARALYSIS.

In the *Lancet*, Dr. Tuckwell reports the following peculiar and instructive case: The patient, a woman aged 30, was married and had had two children. The last pregnancy was twelve months prior to admission. No distinct history of syphilis could be obtained, but there were very strong reasons for suspecting that she had been exposed to the infection. She had never been ill before in her life, except with slight sore throat some fifteen years before. Upon rising in the morning of the day on which her illness began she felt perfectly well, but during the day had aching pains in her ankles and legs, and she noticed that her legs gave way when she tried to walk, so that she was unable to go up stairs at night. For the first week her hands and arms were unaffected, but after that time they gradually lost power, without any numbness or unusual sensations in them. She was well nourished; there was no muscular atrophy. Below the knees there was complete anæsthesia, both to tactile and painful sensations. It also extended above the knees, but was less marked on the outer side of the thighs. Over the region of the buttock she could feel quite well, the area of normal sensation joining that of anæsthesia, about the level of the great trochanter. The fingers of both hands were anæsthetic. The feeling in the palms was diminished. She could feel and localize fairly well on the backs of the arms. The patellar tendon-reflex was abolished, and there was no ankle clonus. The pupils were not dilated and reacted well to light. There was no reaction in the legs to faradization. The patient slept well, appetite good, temperature normal. The heart, lungs and other portions of the body were healthy. The urine was free from albumen, and she had perfect control over the sphincters. The loss of sensation gradually progressed. Three weeks after admission she had a convulsive attack which began with twitching of the right hand and right side of the face, and which passed off, leaving the legs rigid. This rigidity disappeared the next day.

Ophthalmoscopic examination showed well marked optic neuritis in the left eye, clouding of the retina around the disc and swelling of the disc itself. The arteries could scarcely be seen; the veins were large. Right eye: the outer half of the disc was obscure, the inner half dull; veins large, arteries indistinct. She was treated with large doses of iodide of potassium and galvanism, and it is recorded that after eight months her condition has improved much in every particular, and the improvement is continuing.

SYPHILITIC DEFORMITY OF THE TEETH.

Before the Odontological Society of Great Britain (*Medical Times and Gazette*) Mr. Ackery showed two cases of unilateral syphilitic deformity of the upper central incisors; in each case the left central showed the typical notch while the right was normal, which possessed some interest

as an unusual occurrence, since nearly all syphilitic manifestations are bilateral. Mr. Coleman presented a model of a case in which there were two supernumerary centrals of distinctly syphilitic type, while the proper centrals, which were coming down within the arch, were well formed. The patient presented other evidences of syphilitic taint. Before a meeting of the same Society (*British Medical Journal*) Dr. B. W. Richardson read a paper on "*The Causes of Dental Caries, Constitutional and Local.*" For some years he has kept a record of the condition of the teeth of all patients that came before him. He found that, of over four thousand persons, of both sexes and all ages, over eighty per cent. were affected more or less severely with dental caries; while it was rare to meet with a person in whom both sets of teeth were altogether free from the disease. The two general causes which he believes to be chiefly responsible for this condition of affairs are hereditary syphilis and dyspepsia. With regard to the first, he quoted the statements of Professor Gross and Dr. Holland, respecting the proportion of the adult population of the United States and Great Britain, respectively, who acquire the primary disease, estimated in each case at about one in eight. Contracted in adult life syphilis does not materially affect the teeth; but the hereditary constitution bequeathed by it is undoubtedly indicated in the next generation by disease of the teeth, and by a constitutional condition in which caries is readily developed. It is hard to say whether dyspepsia should be placed before or after syphilis in point of importance.

ASSOCIATION OF TABES DORSALIS WITH SYPHILIS.

In the course of an interesting article on this subject, by Dr. Thomas Buzzard, in the *Lancet*, he says that when writing upon syphilitic affections of the nervous system, in 1871, he included progressive locomotor ataxy among the nervous affections belonging to the tertiary stage of syphilis; but since that time circumstances have so altered his views as to make him now entertain some doubt as to the relationship of cause and effect in these two diseases. His reasons for becoming skeptical he gives as follows:—

"Erb, in a recent publication, says that out of forty-four cases he had met with a history of syphilis in twenty-seven. Out of fifty-three cases of my own, a probable history of syphilis is noted in twenty five, but I have reason to think that this figure may not accurately represent the actual proportion, my notes of several of the cases being imperfect. Now, if we add together the statistics of Fournier, Erb, and myself, we shall find that in seventy-six cases out of one hundred and twenty-seven, or in 59.8 per cent., there was a history of syphilis.

"It is clear that coincidence is not sufficient of itself to establish anything like a necessary relation. It might turn out, for example, that a relation of the following kind existed: Tabes dorsalis was formerly supposed to be due to sexual excesses; the individual addicted to sexual excess would be, *cæteris paribus*, more exposed than another to the chance of syphilitic infection, and the misfortune attributed to the latter might really be due to the former. I do not support this view; on the contrary, I do not think there is any ground for believing that sexual excess is, at all events, a frequent antecedent of tabes, but I mention it as an illustration of one mode in which there might be a coincidence in the occurrence of syphilis and tabes without any real association of cause and effect. There may be others.

"It is necessary also to bear in mind another very possible source of fallacy. There is often great difficulty in ascertaining the date of the earliest symptoms of tabes. There may have been some slight flying pains which have left little or no mark in the recollection of the patient, and in nine cases out of ten have been set down by him to rheumatism. Yet these pains, usually the earliest evidences of tabes, may have occurred *before* he became infected with syphilis. In the case of a gentleman whom I have at present under occasional observation there were neuralgic pains in the head some years before he acquired syphilis. Who knows whether these did not depend upon sclerosis of the deep root of the fifth nerve, as is probably the case in the patients whom I showed at a recent lecture? On this account I do not think my statistics are to be depended on, as showing with any certainty the proportion of cases in which syphilis was acquired before the earliest symptoms of ataxy, and it is evident that the same objection may possibly apply to the figures collected by others. The discovery made by Westphal, that absence of patellar tendon-reflex is a very early symptom of tabes, will help us greatly in the future in regard to this subject, but it necessarily throws no light upon the date of origin of those cases the notes of which were taken before his all-important observation became common knowledge.

"The position of tabes in regard to syphilis is peculiar in another respect. Affections of the nervous system which owe their origin to syphilis are not, as such, distinguishable in any very evident manner from diseases unconnected with such infection. The hemiplegia which results from thrombosis of a cerebral artery affected with syphilitic disease follows the same course as hemiplegia consequent on thrombosis of a cerebral artery thickened by atheroma. Syphilitic new formations in connective tissue bring about symptoms depending on lesion of nervous structure, such as might be referable to growths of any other kind. But there are two points especially which frequently afford strong presumptive evidence as to the syphilitic nature of a certain affection. In the case of lesions referable to thrombosis of a cerebral artery there is the age of the patient. Should this be much below that at which degenerative changes may be reason-

ably looked for in the arterial system, there being at the same time no evidence of changes in the heart or kindeys, I think we may almost certainly refer the arterial thickening to syphilis. So also in regard to growths. As a matter of experience, it is certain that almost all cases of marked paralysis of single cranial nerves (I exclude here the incomplete and transitory paralysis seen in tabes) are due to syphilis. When along with this are conjoined symptoms which can only be referred to in the existence of another distinct lesion (one causing—*e. g.*, hemiplegia, monoplegia, or paraplegia), the evidence is greatly strengthened. It becomes, indeed, so strong, and the chance of exception due to the presence of tubercle or cancer is practically so small, that, in the absence of the strongest corroborative evidence of the latter diseases, we should be culpable in treating the case otherwise than as one of syphilis.

"But in tabes the circumstances are very different. Take, for example, the question of age. If we compare the ages of tabetic patients in whom inquiry elicits a history of syphilis with those in which this element is wanting, we are not struck by any marked constast. When we meet with the case of a young man of twenty or thirty years of age who has hemiplegia apparently resulting from cerebral thrombosis, and in whom there is no history of rheumatic fever, heart or kidney disease, we know at once that his disease is almost certainly the result of syphilis. We are struck by the fact that he is suffering from an affection brought about by disease of his cerebral arteries. The more ordinary cause of such disease is the atheromatous thickening which comes in association with other degenerative changes brought about by agedness. Syphilis induces changes in the arterial coats, which lead to a precisely similar result. The indications are simple enough. But in tabes we are left without aid from this question of age. The disease is one commonly of adult life, which most often commences, so far as we can judge, in the period between maturity and middle age, and whether there is a history of syphilis or not, the large majority of patients are about this time of life.

"There remains the question of sex, consideration of which may help us a little. My personal experience is that only 10 out of 100 patients suffering from tabes belong to the female sex. Gowers thus refers to the point: 'Whatever it is which determines the occurrence of locomotor ataxy in men and very rarely in women, and which must be regarded as one of the causes of ataxy, operates in conjunction with syphilis in confining the syphilitic ataxy also to men. Other consequences of syphilis occur in women as well as in men; ataxy in men almost exclusively.' Some years ago, in view of a coming discussion on syphilis at the Pathological Society, I tabulated 100 cases of disease of the nervous system dependent, so far as could be determined, upon syphilis. From this list all cases of tabes were excluded. Sixteen out of the 100 patients were females, but I have since had reason to think that the proportion of females affected with disease of the nervous system consequent upon syphilis is far greater than this. Again, the occurrence of tabes in females of good social standing is surely of extraordinary rarity. Are females of this class equally exempt from syphilitic affections of the nervous system of a kind which is generally recognized? I am sure that they are not, and that in this respect there is a very striking contrast.

"If tabes be very frequently of syphilitic origin, how is it that females, who bear their fair share of other diseases of the nervous system of specific origin, furnish only ten per cent. to the ranks of the former disease?

"While it appears to me incontestable that there is a remarkable frequency of association between syphilis and tabes dorsalis, I do not think, all things being considered, that the time has yet arrived for us to draw safe inferences as to the precise nature of the relation."

TREATMENT OF SYPHILIS.

Dr. G. H. Fox read, at the New York Materia Medica Society, a paper on the treatment of syphilis, in which he lays down the following propositions:—

1. Mercury is the most valuable curative agent of which we have any knowledge. The positive results which follow its employment are such as to convince any competent observer as to its efficacy. 2. It is, however, an overrated remedy; for, while it will lessen the manifestations and shorten the natural course of syphilis in most cases, it will not always produce a speedy and beneficial effect, as generally believed. 3. Patients would derive great benefit if more value were attached than at present to hygienic measures, instead of relying solely on the specific action of mercury. "Remedial agents often acquire a fictitious value by reason of the fact that patients improve during their administration. We know that mercury is not inert, and have ample proof that it can accomplish a great deal. The improvement which takes place in patients is not wholly the effect of the mercury, but is in great measure due to the *vis medicatrix*." 4. Mercury is not essential to the cure of syphilis. The disease has a tendency to run its course, and in the majority of cases is far less malignant than it is supposed to be. If the patient is of sound constitution and the infection is mild, it usually runs its course without injury to the health. "It may be said that such patients will suffer more from severe lesions in later years. I believe that these patients are as thoroughly cured as those who have taken mercury." 5. The internal administration of mercury is preferable to its use in the form of inunction, vapor-baths, etc., in all cases of constitutional disease. 6. The dose of mercury usually given is too large. "In my own experience I have never seen any benefits result from the combination of various salts of mercury, as recommended by Bumstead, or by the frequent change from one preparation to another." 7. The duration of mercurial treatment should vary according to the character of the case. There are cases of mild and cases of severe syphilis. Mild syphilis does not require mercurial treatment. "There are cases which demand two, three, or perhaps five years of treatment. But it is utterly impossible

to fix a certain time as the duration of treatment in all cases. . . . . My own practice is to give mercury in every case during the existence of any symptom of the disease, whether it occurs early or late. In the early period I continue it for six months after the last symptom has yielded ; I then stop it, and await further developments. If the symptoms reappear, I revert again to mercury, and continue perhaps for two or three months after the disappearance of the latest symptom. In late syphilis I give mercury to subdue any growing symptom, and then stop."

Of iodide of potassium, Dr. Fox has a high opinion.

"I believe that in the early stages of syphilis it is an invaluable therapeutic agent. In the stage of efflorescence, I must admit that the drug has little or no effect upon the cutaneous manifestations. In ulceration of the tongue and mucous patches, I have seen good results following its use, when mercury had been given for several weeks, with no effect. In the cure of cephalalgia and arthritic pains, associated with the first outbreak of syphilis, it displays its remarkable power. Of its great value in late syphilis, I need not speak. Its power is often exerted in a most brilliant manner when its administration is preceded by a course of mercurials. The iodide is best prescribed in an aqueous solution, a cubic centimeter containing one grain. It is a remedy which no patient ought to be compelled to take for a great length of time. It does its work quickly or not at all, and when unnecessarily continued, is sure to do harm. For every case of syphilis that I have seen benefited by immense doses of the iodide, I have seen at least two in which large doses have done harm. I do not deny the value of large doses in certain cases, but I protest against the continuance of large doses in chronic syphilis. When there is dyscrasia and a weakened state of the digestive organs, I have great faith in the iodide of starch."

"Iron in the treatment of syphilis is of very great value. It deserves to be ranked with mercury and the iodide. Its power to combat the anæmia which is invariably present in the early stage of syphilis renders it a most invaluable adjunct of mercury. I should prescribe it for a patient presenting chancre or initial lesion, and give it as a routine in the secondary lesions. It tends in a slight degree to lessen the probability of subsequent manifestations. In the weakened state of the system, asociated with late syphilis, the value of iron is too well known to require mention ; but in the early stage of the disease its value seems to be unknown or unappreciated. I employ the tincture of the chloride in daily doses of ten to fifteen drops. Cod-liver oil is a remedy which is not unfrequently of service. When an individual with a strumous diathesis is affected by this disease, its symptoms are apt to be severe and prolonged, and amenability to mercury is greatly lessened. In these cases the use of cod-liver oil alone, or in connection with iron, is likely to be productive of good results. In late syphilis of an ulcerative type I have repeatedly seen mercury fail to do good at first, while after the administration of the oil for a month or two it has accomplished all the good that could be expected from its use."

In the discussion which followed, Dr. Sturgis observed that although many cases of syphilis will get on very well without mercury, there is a risk for the future incurred by not giving it, for it is impossible to say whether the case will turn out well or ill. He has a much higher opinion of inunction as a means of administering mercury than Dr. Fox ; but he believes that the value of iodide of potassium as a curative agent has been much overrated, although it forms an excellent adjuvant. He has found the iodide of starch so unsatisfactory that he has abandoned its use. As regards the combined use of mercury and the iodide, he believes the effects attributed to the iodine are really due to the mercury, the iodine seeming to favor the solution of the mercury and render it more active. Thus, after a course of mercury and iodine, slight ptyalism and diarrhœa may be produced, while no such results had followed when mercury had been used alone.

Dr. Johnson agreed with Dr. Sturgis in believing that the iodide renders mercury which had remained inactive in the system for a time much more active. It acts in an analogous manner with regard to lead, in poisoning from which it is not infrequently administered. By prolonged use it helps to eliminate the lead, although the first stage of its action is to increase the activity and poisonous effect of this.

Dr. Castle, in using the iodide, either alone or with mercury, generally in the later stages of the disease, has had the objects in view of inducing the absorption of pathological products, and the relief of the pains which occur at the later stage of the malady ; and he does not believe that iodine in any form exerts any other specific effect. As soon as it is eliminated its effect ordinarily ceases, and to secure this it must be continued for some time. He agrees with Dr. Fox regarding the different ways different persons are affected by symptoms, and has met with many very mild cases : but he has treated these also with mercury, with a view rather of preventing subsequent developments than because their condition at the time required active medication. In such cases, as in those that are more severe, he has combined it with the use of tonics, and as thorough an attention to hygiene as practicable, believing this quite as important as any specific treatment.

Dr. Morrow observed that, in the general habit of treating syphilis with mercury and iodine in all its stages, he had also treated many cases without mercury, and had been unable to detect any

difference in the evolution of secondary symptoms in either set of cases. He also pointed out the fact that a much longer course of mercurial treatment (at least four years) is now deemed to be required for protection from subsequent manifestations than was considered necessary some twenty-five or thirty years ago, when a course of six or twelve months was regarded as sufficient. This would seem to show a growing lack of faith in the curative properties of mercury.

Correspondence.

Heat Fever.

Ed. Med. and Surg. Reporter:—

As the hot weather is now upon us, and the evil effects of high temperatures will have to be met and combated by the profession, I have thought the history of the following case of (shall I call it?) heat fever, might be interesting to the readers of your journal:—

August 27th, 1881, D. called upon me at my office, and asked me to go and see his child, a girl, aged three and a half months, in consultation with Dr. X. D. said his child was in convulsions and that he did not think it would live an hour. I went with him at once, and upon my arrival I found the child in convulsions, wrapped in a big shawl, mustard plasters on its back and feet, in a very small room, crowded with distressed and sympathizing neighbors and friends, a big fire in the cook stove in the kitchen and the temperature of the little sufferer 108° F.

Although the windows of the room were hoisted, the air was very hot and oppressive. The thermometer indicating a temperature of 90 to 100° in the shade. I ordered the child to be taken out of the room on to the porch, stripped of all its clothes, the mustard washed off its back and feet, and its body wrapped in a single layer of muslin, wrung out of cold water, to facilitate the rapid cooling of the child. I directed it to be fanned constantly. On the porch Dr. X. tested the temperature of the patient and found that it was 107° by his thermometer. As the porch adjoined the kitchen, where the hot stove was, I directed the child to be taken into the yard, in the shade of the house, and that cloths saturated with alcohol be substituted for the cold water applications, as it tended to more rapidly cool the patient. All this time the child was working in convulsions. The advantage of ordering the baby into the yard was apparent to all, viz: cooler and purer air, and a better opportunity for those sympathizing friends to observe all that was going on, to satisfy their curiosity without in any way adding to the discomfort or peril of the little sufferer. Steadily persevering in the application of the cloths saturated with alcohol, and the fanning, I had the satisfaction of seeing the temperature of the child gradually fall to 96°, and, *pari passu* the subsidence of the convulsions, until, when the temperature had fallen to 96°, the convulsions had altogether ceased. I then discontinued the applications and the fanning. The temperature soon rose above the normal again, and as it rose the symptoms of the recurrence of the convulsions reappeared. By reapplying the cloths saturated with alcohol, and by fanning, to increase the rapid evaporation of the alcohol, and thereby more rapidly reduce the temperature, the convulsions were controlled, and the heat of the body kept about normal. Attention to the diet and remedying the irregularities of the digestive organs, finally restored the little patient to comparative health, although she is still unable to walk.

Death from Morphia without Narcotism.

Ed. Med. and Surg. Reporter:—

I was called, April 28th, at 8 A.M., to Mr. H., aged 27, married, occupation conductor. I found him vomiting violently, not able to retain the smallest quantity of anything on his stomach. Frequent discharges from the bowels, cold extremities. Pulse 160. Respirations 24. Suppression of urine. Pupils strongly contracted.

As he had, a month previous to this, taken morphia with suicidal intent, and suffered from the same symptoms, I suspected an overdose of morphia again, and upon inquiry found that he had taken twenty grains of morphia the evening before, which did not produce sleep. Nor was there either narcotism or delirium throughout the case. There was no change whatever in any symptom except increased heart action and cyanotic appearance of the extremities. He died 4 P.M. the 30th. It is not necessary to give my treatment in the case; suffice it to say I used neither atropia nor any preparation of belladonna. On account of the peculiar symptoms some of the medical gentlemen who were with me in the case suspected other poison than morphia. Accordingly we removed the stomach May 1st. Three weeks later it was sent away for analysis, which threw very little or no light on the matter, as no poisonous material of any nature could be detected.

I have frequently been called to patients who were suffering from large (but not fatal) doses of morphia, with very little narcotism, but have never met with a case before which resulted in death without narcotism, diminished respirations, and other symptoms generally produced by overdoses of opium and its preparations.

News and Miscellany.

Darwin's Death.

From a speech which Virchow made last month, in a meeting of the Berlin Anthropological Society, in reference to Darwin's death, we glean the following concerning the last hours of the great naturalist:—

Darwin died from an affection of the heart, from which he had been suffering for years, but which, till a few days before his death, had not been considered as dangerous to life. Until two

weeks before his death Darwin used to leave his house and take a walk, notwithstanding he commenced to feel very weak. He still continued his favorite work, and the day before his death he examined a plant. About half-past eight o'clock in the evening he was carried to his bedchamber, where he sat up some time, reading. Toward midnight he was seized by a severe spasm, which, notwithstanding the most attentive treatment, caused his death at four o'clock in the afternoon.

Milk Sickness.

The mystery which surrounds milk sickness cannot be said to have been removed by the late investigations of Dr. James Law, published by the National Board of Health. He, however, believes that it is characterized by the presence in the blood of a species of spirillum, resembling that seen in relapsing fever. The germ is probably derived from drinking water, or from the surface of vegetables, as certain wells are said to infect with certainty, and the disease has been repeatedly produced by feeding upon particular plants (*Rhus toxicodendron*, etc.) That these plants in themselves are not the pathogenic elements, is shown by their innocuous properties when grown in places out of the region of the milk-sickness infection. Dr. Law thinks it altogether probable that here, as in malignant outbreak, we are dealing with a micro organism which has developed pathogenic properties, and which can be produced indefinitely in the bodies of living animals.

We should be glad to print further observations on this disease from some of our Western readers.

American Dermatological Association.

The Sixth Annual Meeting of the American Dermatological Association will be held at Newport, R. I., on August 30th, 31st, and September 1st.

Embalming.

The principal Italian embalmers keep their special processes a secret, although the chief steps are well known. The process of embalming is stated to consist of five steps. First, cold water is injected through the whole circulatory system until it issues quite clear; this may take as long as five hours. Alcohol is then injected, for the purpose of abstracting all the water from the body; this is followed up by the injection of ether, to dissolve out the fatty matter; this injection is carried on for several hours—in thin subjects for two, in very fat ones for even so long as ten hours. After this a strong solution of tannin is slowly injected, and full time is allowed for its soaking into all the tissues; this takes from two to five hours. Lastly, the body is exposed, for from two to five hours, to a current of warm air, which is previously dried by passing it over heated chloride of calcium. The body can then be preserved for any length of time without undergoing change, and is as hard as stone.

Items.

—The *Canada Journal of Medical Science* says:—

"In a curious old work, published in 1824, entitled 'Nugæ Chirurgicæ,' by Wm. Wadd, Esq., F.L.S., we find the following account of Cordus, a physician of eminence, who died in 1535: 'Cordus, who was accustomed to receive his fees only at the termination of his patient's disease, describes, in a facetious epigram, the practitioner at three different times, in three different characters:—

'Three faces wears the doctor: when first sought,
An angel's; and a god's, the cure half wrought;
But when, that cure complete, he seeks his fee,
The devil looks then less terrible than he.'"

MARRIAGES.

BULLARD—SUEDMEIR.—On Wednesday, June 21st, 1882, at the residence of the bride's parents, by Rev. T. T. Holton, of Lincoln, Ill., Dr. Frank B. Bullard and Miss Kate Suedmeir, both of Chestnut, Ill.

DALSEN—SMITH.—On July 8th, 1882, by the Rev. R. F. Alsop, Charles W. Dalsen, M.D. and Laura V. Smith, both of this city.

DENNIS—LODER.—In this city, on Tuesday morning, June 20th, at the residence of the bride's brother, Dr. Percival E. Loder, by the Rev. Achilles L. Loder, of Gunnison, Colorado, Dr. D. N. Dennis, of Killingly, Conn., and Miss M. Camilla Loder, of Philadelphia.

PROPER—ANDRE.—June 1st, 1882, at Mr. Wesley Cramer's, near Franklin, Pa., by Rev. T. D. Stewart, Dr. Walter J. Proper, of Wallaceville, Pa., and Miss Clara A. Andre, of Hendersonville, Pa.

RIMER—HESSON.—In West Philadelphia, June 21st, by Rev. J. Addison Henry, D.D., J Thomas Rimer, M.D., of Clarion county, Pa., and Carrie Adele Hesson, of West Philadelphia.

SIMPSON—PRATT.—On Tuesday, May 23d, by Rev Andrew Lees, George W. Simpson, M.D., of Mill Creek, Huntingdon county, Pa., and Miss Hattie L. Pratt, daughter of Henry M. Pratt, Esq., Philadelphia, Pa.

SNOW—LOCKWOOD.—July 6th, 1882, at New-Canaan, Conn., by the Rev. Joseph Greenleaf, Dr. Gustave N Snow, of Hartford, Conn., and Josephine H., daughter of John W. Lockwood, of Philadelphia, Pa.

SWIFT—JACOBS.—In New York, on Tuesday, June 13th, at All Souls' Church, by the Rev. Russell N. Bellows, Marie Aborn, daughter of the late Samuel J. Jacobs, and Dr. William J. Swift.

VREELAND—LOCKWOOD.—At Westtown, N. Y., June 8th, by the Rev. R. Bowen Lockwood, assisted by the Rev. J. B. Fisher, J. S. Vreeland, M.D., of the above-named place, and Miss Kate Lockwood, daughter of the officiating minister.

WEBER—CASSELBERRY.—On Thursday evening, May 25th at the St. James' Perkiomen Church, by Rev J. L. Heysinger, Dr. Mathias Y. Weber and Miss Ann Rebecca Casselberry, both of Evansburg, Montgomery county, Pa.

WEISMANN—WISNER.—On Saturday, July 1st, 1882, by the Rev. Chas. Frincke, of Port Richmond, S. I., Francis H. Weismann, M.D., and Louise Wisner, of Chicago, Ill. No cards.

DEATHS.

FOSTER.—Dr. Nathaniel Foster, an old and eminent physician of Cincinnati, Ohio, died, July 16th, of paralysis. He was a brother-in-law of the late General W. H. H. Lyttle, and was well known throughout the medical fraternity of the Union.

180-eowtf

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

SUDDEN DEATH IN TYPHOID FEVER.

BY M. BLACHEZ,

Physician to the Hôpital Neckar.

Gentlemen: This accident is by no means rare. Already more than one hundred observations are on record, and yet, until within the past fifteen years, this mode of termination has hardly been noticed in French works on the subject. Chomel and Andral each mention one case, but without devoting any particular attention to the subject.

In 1864 Zenker (of Leipsic), in a memoir on the muscular lesions observed in typhoid fever, insisted on the degeneration of the muscular fibres of the heart, a condition already noticed by Lænnec and Louis, and particularly by Stokes, in malignant typhus. The subject had then attracted little attention, until M. Dieulafoy made it the subject of his thesis, in 1869.

Since then the researches have been numerous, and the same year appeared the work of Hayem on the muscular alterations in febrile conditions. Among the other works relating to the subject are the memoir of Laveran, in the *Archives de Médecin* for 1871; several articles by Liebermann which appeared in the *Gazette des Hôpitaux* in 1877; the thesis of M. Tambareau and that of M. Rabère (1878), in which sixty observations are analyzed. All the necessary indications may be found in a memoir by M. Huchard, which appeared in the *Union Médicale*, in 1877; in this work all the theories brought forward to explain the sudden death are analyzed and discussed.

I have been led to study over the literature of the subject by the observation of a case where I suffered a sad surprise.

The fatal termination in this case supervened under somewhat different conditions from those usually observed. We will give the observations in detail, and end by certain considerations suggested by it regarding the mechanism of sudden death in typhoid fever.

Obs.: Mme. X., thirty-five years of age, tall and thin, delicate while a child, but enjoying fair health since her tenth year. She has had three children, of whom two are living and in good health. She is in comfortable circumstances, living in the country. On Feb. 22d she suffered from slight malaise attributed to a cold contracted at the theatre.

There was slight fever, with the ordinary symptoms of gastro-intestinal derangement. No benefit was experienced from an emetic, and slight diarrhœa supervened.

Notwithstanding her slightly febrile condition, Mme X. was able to preside at a dinner of twenty persons on Feb. 27, and partook, without nausea, of light food.

On the next day, however, the diarrhœa was more troublesome, the matters passed being slightly tinged with blood; there was also slight griping. This diarrhœa very soon ceased under the influence of treatment. After March 2d there were three stools daily, of almost solid consistence and dark colored.

The pulse oscillated between 84 and 92 per minute; the temperature never went above 100° C., in the evening and fell in the morning to the normal standard. There was no pain on pres-

sure over the abdomen, no meteorism and no spots.

The tongue was red and the papillæ prominent; no râles in the chest.

Notwithstanding that the general symptoms did not seem to be of great gravity, the patient complained of being excessively feeble. She was very much depressed in mind and dreaded a fatal termination. She refused any sort of substantial alimentation.

He first considered it a case of gastro-intestinal catarrh, prolonged and aggravated by the dinner of February 27th, but on March 4th a few cuticular, rose-colored spots appeared on the belly. There was on several occasions very slight epistaxis. The diagnosis was no longer doubtful, and extract of quinquina, in potion, was ordered.

On March 5th she passed a good day, was able to take some light soups and milk, and remained in a pleasant frame of mind all day, the temperature remaining at 100.4°. On the morning of the 6th she woke about seven o'clock, after a tranquil night, and told her husband that she felt well but very weak. She asked for a glass of milk, and hardly had it swallowed when she complained of sickness at the stomach and desire to use the stool. It was brought to her and she was just about to use it when she fell back on the bed, and died without a struggle, after a slight contraction of the lips.

Every means of resuscitation were employed without success; the heated hammer was applied and energetic frictions with mustard over the entire cutaneous surface.

Death was instantaneous and without the occurrence of any apparent hemorrhage.

This was evidently a case of death by syncope; the hypothesis of an embolus, which first presented itself, was untenable, as there had been no dyspnœa or apparent asphyxia.

Comparing this case with others of the same kind contained in the works we have mentioned, we remark many points of similarity, but some also of difference.

In the first place, in most of the cases here recorded, where sudden death supervened, it occurred during the period of convalescence. It is at this period, when the disease is supposed to have terminated and the patient on the road to definitive cure, that death brutally supervenes to destroy the best founded hopes.

There is one observation only recorded by Liebermann where death occurred on the sixth day. In this regard our case differs from those ordinarily observed, for it is impossible to carry the debut of the malady further back than February 22d, and it was on March 6th, that is, on the twelfth day, that death supervened.

We observe that the authors concur in the opinion that these sudden deaths seem to supervene chiefly in the milder forms of the disease. This circumstance is habitual but not absolutely constant. From this point of view it would be difficult to meet with a milder case than the one we have reported. The temperature, observed with care, was never higher than 100.6°; the patient was able a few days after the début to preside at a dinner which lasted two hours, and the very day preceding her death the general condition was so good and she recovered her appetite so well that we were inclined to believe ourselves in presence of one of those abortive forms of typhoid fever observed in acclimated subjects living under good hygienic conditions.

The rather varied explanations given for the occurrence of sudden death in typhoid fever, and which have been so well discussed by M. Huchard, may be ranged under three principal heads: 1st. The theory of reflex action (Dieulafoy); 2d. That of cerebral anæmia (Laveran and Bussard); 3d. The theory of myocarditis (Zenker); that of myocarditis with proliferating endarteritis (Hayem).

In the first theory the reflex action would have as point of origin the intestinal lesion. The excitation is transmitted through the sympathetic nerve to the cells of the medulla and bulb. There it is transformed in motion, following sometimes the course of the pneumogastric, sometimes that of the other respiratory nerves, whence the arrest of the respiration or of the action of the heart.

This ingenious theory, based, according to the author, on physiological and clinical facts, is with difficulty sustained against the objections brought forward by M. Huchard.

In effect, according to this hypothesis, death should correspond with the period when the lesions are most marked, and not with that of their reparation. Syncope again is not observed in certain maladies where the nerve filaments of the sympathetic are seriously inflamed, as in peritonitis and dysentery. Sudden death has been frequently observed in typhus fever, when the intestinal lesions were wanting. For these reasons the hypothesis of reflex action, having its origin in the intestines, is, at least, insufficient of itself to explain the occurrence of sudden death in typhoid fever.

As regards the theory of cerebral anæmia, it does not account for the persistence or gravity of

the syncope in typhoid patients. Cerebral anæmia exists in many cases of marked cachexia where syncope succeeds on syncope without causing death.

It is well known, also, that the bulb and middle brain (mesocéphale) which have so direct an influence on the circulation, conserve their functions in the most marked cases of encephalic anæmia, on account of the very free vascular anastomosis of blood vessels existing in these portions of the brain substance.

The very great importance of the muscular lesions in the various fevers, particularly in typhoid fever, cannot be contested.

Hayem has shown how much this fatty, granular degeneration, studied by Zenker and Waldeyer (1864 1865), is promoted by a peculiar alteration of the blood vessels, which he has made known under the designation of proliferating endarteritis; this endarteritis causing the obliteration of the small arteries supplying the muscles of the heart itself, through the production of small thrombosic clots.

The principal objection brought forward against this theory is the fact that the cardio-vascular alteration described was wanting in several cases where it had been sought for with the greatest care.

M. Hayem affirmed, it is true, that he has in all cases found this alteration of the muscular fibres of the heart in cases of sudden death in typhoid fever. But it should be remarked that in the cases of variola where MM. Desnos and Huchard found analogous alterations, sudden death is much more rare than in typhoid fever; a fact due, perhaps, to the relatively short duration of smallpox.

We have not yet spoken of the thrombi or emboli found in analogous cases. The cardio-vascular degeneration and the peculiar state of the blood, evidently are of importance in the production of these coagulations; but they are far from being constantly found, and kill rarely by syncope, but rather by asphyxia, more or less rapid.

It may be concluded from this summary exposition, that the anatomical explanation of sudden death in typhoid fever is yet far from being satisfactory. There is no reason to believe in any one exclusive theory. M. Huchard is of opinion that the anæmia of the brain, taken in conjunction with the degeneration or simply ischæmia of the heart, will explain the occurrence of this symptom in most cases. Whatever the theory, is it not remarkable to observe these fatal syncopes supervene in cases so different from a clinical point of view?

If the period of convalescence seems to be that of predilection for these sudden deaths, it is none the less true that these symptoms are observed more frequently in mild than in more serious cases. Or, it would seem that the various degenerations noted as causes of sudden death should be much more marked in subjects worn out by a long morbid process and all the symptoms incident thereto.

And yet the patient in our observation was in excellent health twelve days before her death. The fever was exceptionally mild. It is difficult to suppose the existence of any advanced cardiac alteration in a woman who had always enjoyed good health, and who, during her short illness, had presented no trouble of the circulation except feebleness of the pulse, but without any intermittence or irregularity.

This intermittence of the pulse with tendency to syncope had been remarked in many cases as precursors of sudden death. We were struck by the extreme discordance between the benign and almost apyretic malady and the extreme lassitude, pallor, and in fact, almost collapsed condition of the patient.

On this account, from the first days, we renounced every form of debilitating treatment, and administered wine, quinine and coffee.

This conduct is recommended by all the authors who insist on the employment of every possible means to sustain the strength of the patient.

We were very far indeed from expecting, with but just the symptoms ordinarily observed in nervous impressionable subjects, the sudden and, as it were, brutal termination, supervening in a young, vigorous and long acclimated patient, living under the best possible hygienic conditions.

Communications.

THE LATE EPIDEMIC OF CATARRHAL FEVER IN PHILADELPHIA.

BY HUGO ENGEL, A.M., M.D.

Since the beginning of March of this year our city has been visited by one of the severest epidemics of catarrhal fever that has ever played havoc among the sedate inhabitants of the Quaker City; severe less on account of the number of its victims—death being generally caused by that fell destroyer and boon companion of influenza, pneumonia, or by the disease attacking the aged and those enfeebled by chronic ailments—but severe on account of the tenacity with which the *grippe* held on to the banks of both Delaware and Schuylkill, and on account of the ever vary-

ing symptoms under which this baneful complaint chose to manifest itself.

While one person, when suffering from this disease, would sneeze and sneeze, till his stock of handkerchiefs was exhausted, another complain of intense headache, a third of a stitch in the side, a fourth of an irritable cough, a fifth of pain in the stomach and nausea and vomiting, a sixth, perhaps, of disturbance in respiration and restlessness at night, they all very soon experience certain symptoms alike: fever, with an increase of temperature to 102°–104½° and an indescribable weakness, which seemed to befall the mental faculties as well as the motor impulses and the muscular system, while the afferent nerves were wide-awake and carried impressions with a rather painful vigor to the general centre of common sensation. The fever would occasionally commence with chilly sensations, and mostly reach its acme within two or three days, and usually continue at the height gained, with slight morning remissions in favorable cases, till the beginning or end of the second week, when more or less defervescence would indicate the anxiously looked for but frequently tedious convalescence. The general debility set in very early, and twenty-four hours after the appearance of the initial symptoms an apathy could be observed in the patients, which rarely shows itself so early in any other disease —indigestion from over-indulgence in not strictly temperate drinks perhaps excepted. Gloomy forebodings, occasional delirium, sleeplessness, were so many indications of the disturbed condition of the brain, while the often most intense headache, the severe neuralgia, and the not less painful hyperæsthesia, showed the irritable state of the sensory nervous system. In the vast majority of cases the progress of a poisonous substance along the mucous membrane of the whole respiratory tract could, during the course of the disease, be plainly traced; mostly beginning with irritation of those fibres of the fifth nerve that spread over the Schneiderian mucous membrane of the nose, occasioning sneezing and discharge of mucus from that prominent organ; this was followed rapidly by a mild sore throat, which in turn was succeeded by coughing, and the careful auscultator could frequently hear the mucous and dry râles becoming smaller and smaller from day to day, till a subcrepitant râle left him in doubt if it were not crepitation signifying the engorgement which generally denotes the approach or the first stage of pneumonia. This complication, as we in several epidemics of catarrhal fever had opportunity to note, may be of a threefold character. In the one we have only the subcrepitant râle, then a feeble bronchovesicular murmur over nearly one whole lobe (always the lower) of one side, while on the opposite side the respiration seems harsh, almost puerile in character; the clearness on percussion over the spot of feeble breathing is slightly impaired, but no further alterations are observed except a gradual return to the normal sound, accompanied by free expectoration. It always seemed to us as if in these cases exudation collected in the middle-sized and finer bronchial tubes, and as if there was not sufficient strength in expiration to expectorate the sticky, not as yet liquefied masses, and not power enough in inspiration to fill this lobe with air, which could not easily make its passage through the clogged channels. Such a case I have never seen end in pneumonia, and when the signs mentioned—subcrepitant râles, feeble respiration over nearly a whole lower lobe of one lung and slightly impaired percussion note—were present, it has become my habit, in influenza, to listen more carefully to the other lung, when the harsher breathing would always satisfy me of the existing state of affairs. But if the signs spoken of were confined to a comparatively small part only of a lobe, and the other lung would contain a symmetrically situated and similarly weak place, then I knew that the further progress of the complication would be the development of bronchopneumonia. And if the apparent subcrepitant râle sounded like the well known crepitation, heard best at the very beginning of inspiration, and if this was followed within twenty four hours by a rapidly progressing dullness confined to one whole lower lobe, then I felt convinced that I was unable to prevent—though not to guide—the onward march of croupous pneumonia. The first lung complication is rarely absent in a fully developed case of grippe; the second is often met with in the very young and very old, and *may* lead to serious trouble; the last experience has taught me to consider a very dangerous, and in the old *invariably* fatal, complication of influenza. On account of treatment as well as of prognosis, the distinction of these three lung complications is important.

No matter how manifold the picture catarrhal fever may present, all the forms of this epidemic disease can be classed under one of the following heads:—

1 *The Nasal Variety.*—The individual attacked has chilly sensations, followed by fever of moderate kind and by burning of the eyes, which he continually is forced to rub with his hands,

and a peculiar dry feeling on the Schneiderian mucous membrane. Then sneezing commences and continues for several days with little interruption. The catarrh does not only extend to the mucous membrane of the eyes and nose, but also to that of both antra and of the pharynx and neighboring parts, so that pain over the cheek-bone and sore throat are common. At the same time the patient has the same sensation all over his body as a person after having caught a severe cold, and feels remarkably weak. In some cases the whole surface provided by the branches of the sensory root of the fifth nerve is in a state of hyperæsthesia. This form of influenza, which generally attacks stout and robust men, lasts from seven to twelve days. Quinine in decided doses, and syringing the nose, and washing the eyes with a solution of benzoate of sodium (concentrated for the former, mild for the latter), an even temperature, and nourishing but easily digestible food, constitute the most successful treatment. The inhalation of olfactorium anticatarrhoicum (Hager, Comment. ad Pharmacop. Germanic.) accelerates the cure.

2. *The Neuralgic Variety.*—After some chilly sensations the patient has decided fever and excruciating neuralgic pains, which follow one of the three branches of the sensory root of the fifth nerve, mostly the ophthalmic branch. The integument of the whole head is sometimes exceedingly sensitive, a burning sensation is felt on the skin and the head seems to ache all over. At the same time there are symptoms of a moderate catarrh of the mucous membrane of the eyes and of the nose. This painful form, which if left to itself may last two weeks, affects mostly women and thin persons with a predisposition to neuralgia, and can only be controlled by very decided doses of quinine. Those suffering from this form become very feeble, and a vigorous tonic treatment should be adopted, therefore, from the very beginning.

3. *Broncho-pneumonic Variety.*—Here, chilly sensations, mostly creeping along the spine, are never absent, but of short duration and soon followed by high fever and more or less intense headache and restlessness. The temperature is rarely below 104°. The same feeling of exhaustion and debility which is met with in the other varieties appears here also, and is accompanied by more or less difficulty in breathing, by an irritable cough and pain in one side of the chest. After the disease has, for about five days, presented the picture of a common bronchitis, but with the higher temperature, the pain in the head and the remarkable weakness, it assumes a still graver aspect, and one of the above-mentioned lung complications and sometimes pleurisy makes its appearance. The prognosis depends, as also hinted at above, upon the kind of lung complication and the vitality, strength and age of the patient. It is essential to recognize this form early, so that no depletion, no treatment with tartar emetic, drastics or blisters should be entered upon, but instead of this a tonic regime with ammonia, digitalis and quinine be instituted. Opium and chloral will best relieve the headache, while benzoate of sodium should be inhaled as frequently as possible, by the aid of a steam atomizer.

4. *The Abdominal Variety.*—By chance, I had the opportunity of observing two cases of this kind five or six years ago, when catarrhal fever was also epidemic in our city, and to attend two cases of the same variety this year. The person attacked by it complains of pain in the stomach, nausea and a chilly sensation, succeeded by fever, great thirst, vomiting, constipation and a rapidly developing peritonitis, which runs its usual course, ending, by the beginning of the third week, either in death or in a very slow and tedious convalescence. From the very beginning there exists a remarkable weakness, but the intellect is, even in fatal cases, unimpaired to the last. This variety seems to attack children by preference, and is with them very severe, while adults suffer rarely from it, and then in a milder degree. There are four points of distinction by which this form of peritonitis can be recognized from all the other varieties of peritoneal inflammations: 1. The presence of the epidemic. 2. The absence of any apparent cause, neither the most careful physical examination nor the most searching inquiry into the history of the case throwing any light on the subject. 3. The rapidity of the onset; after the symptoms of a common attack of indigestion have lasted about twelve hours the peritonitis appears, as it were, over night. 4. The great debility of the patient, which accompanies the ailment from the very beginning. In adults the peritonitis is never general, only local in character, and usually confined to the epigastric region. The treatment is the same as that of peritonitis from other causes, with the exception that under no circumstances depleting measures should be adopted. Morphia and quinine, regulation of the diet, feeding by the anus, mercurial inunction into the abdominal walls, benzoate of sodium internally and turpentine enemata have met, in my hands, with the best success.

5. *Latent Variety.*—While influenza is epi-

demic at a place, any patient suffering from any acute or chronic ailment is liable at any time to be brought under the influence of the epidemic. There are two symptoms by which experience has taught us to recognize this influence when brought to bear upon a malady previously existing: a rise of temperature and a general debility; both symptoms appear suddenly and can apparently not be accounted for. The immediate administration of quinine and of benzoate of sodium, and the adoption of a tonic regime in general, are all the therapeutic measures indicated. Whenever this latent grippe attacks persons otherwise already debilitated or old, the prognosis is exceedingly grave. This explains the fact that, while catarrhal fever itself is not a dangerous disease, the mortality rate in a place where grippe is epidemic is greatly increased.

Many other and different pictures have been given of this disease, but a careful examination into the facts of each case that has come under my observation has convinced me that the varieties enumerated are the only ones which can be explained, while all the others belong to the last form (5), where simply the epidemic influence is stamped upon some other complaint.

Let us now look at the etiology of the disease. If we remember the researches of *Klebs*, who followed the bacilli typhosi from the mucous membrane of the nose and the pharynx down the lining membranes of the bronchial tubes to the lung structure itself, and down the whole alimentary tract, and if we think of the Prager epidemic of typhoid fever, during which very few abdominal symptoms were met with and the patients all seemed to suffer from the lung complications only, there cannot be denied the existence of a great analogy between the cause of abdominal typhus and that of catarrhal fever. In the latter we find varieties where the disease seems to be concentrated on the Schneiderian mucous membrane, and the channels and cavities in connection with the nose; then there are cases where we can trace the progress of some irritating substance gradually all along the respiratory tract; and lastly, cases are met with, where the infection evidently has been carried into the system by way of the alimentary canal. I have been able to detect the same infiltration of the mucous membrane, the same perivascular exudation as met with in all infectious diseases, but my microscope was not powerful enough, or my skill in preparing the specimens not sufficient, to enable me to recognize the roots and spores, the existence of which I do not doubt, and I have to leave this research to other hands, more expert in these examinations. Far be it from me to imagine that the bacillus typhus is the cause of grippe; nay, I mean that researches will soon prove that a micrococcus of some kind produces the manifold symptoms of catarrhal fever.

Another proof of the truth of this assertion is found in the different picture the disease presents in different epidemics. Just as the different cultivation of micrococci, the more or less long continued exposure of each culturing fluid to the influence of the atmosphere produces in the animals inoculated with the different symptoms, though always in harmony with each other, so the longer existence of the poison of catarrhal fever in our air, its condition at the time of entrance into the human system, causes manifold symptoms, which, in the main, however, continue the same. An epidemic of influenza starting suddenly in one part of the country usually loses its severity with its further progress, and while the first cases attacked by it in any locality generally are fatal, or at least severer, the longer the epidemic tarries at one place the milder the symptoms it causes become. Not the least reason for this theory I find in the action of such remedies as quinine, salicylic acid, carbolic acid and the benzoates. I prefer the latter, because while being as effectual, they can be given more frequently, and in larger doses, with greater immunity to the human system than is the case with other disinfectants.

507 *Franklin street.*

REMOVAL OF A LARGE INTRA-UTERINE FIBROID BY MEANS OF A NEW INSTRUMENT.

BY THAD. S. UP DE GRAFF, M.D.,

Of Elmira, N. Y.

The history of the case I am about to relate does not differ, in any essential particular, from that usually accompanying intra-uterine fibroids. That which I desire to call attention to is the great size of the tumor, the failures at removal by the usual instruments, and final success by means of a specially devised forceps to meet the requirements of the case.

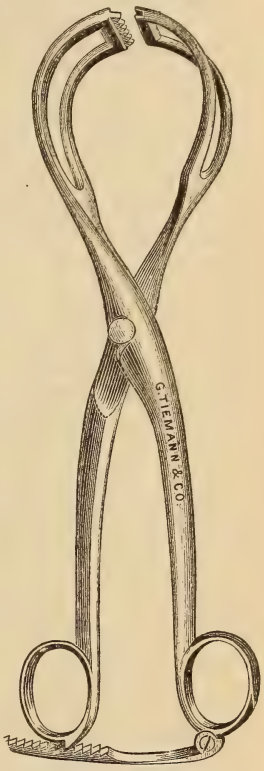
The patient, a married woman, aged 42, sterile, menstruation regular but very profuse. The hemorrhages at the regular menstrual periods had grown, during the past year, increasingly profuse and correspondingly alarming. She had grown so anæmic and weak that the recumbent position, in bed, was an absolute necessity. Finally she came, or was carried, to this city and

placed under the care of a very competent and estimable lady physician, who promptly discovered the cause of the repeated hemorrhages, and recognized the necessity for surgical interference. The patient was too weak, however, to permit of any extended examination, particularly since such a proceeding invariably brought on renewed hemorrhage. After a number of weeks' treatment with tonics of quinia and iron, and subcutaneous injections of ergotine over the region of the uterus, the patient's strength had become so far restored, and the hemorrhages so modified, as to permit of an examination that should ascertain the size and point of attachment of the tumor. By means of a flexible uterine sound, the tumor was found to be attached near the fundus, encroaching somewhat upon the posterior wall of the uterus. It was found to be sessile, with a very broad attachment, and measuring four and one-half inches in diameter. The cervical canal had become obliterated through the pressure exerted by the tumor, while the os was dilated to about three inches in diameter.

This was the condition of affairs at the first consultation, held with a view of determining whether an attempt should be made at removing the growth, and for canvassing the chances for success in such an endeavor. It should have been stated that the patient suffered constant and severe pain, from pressure and weight of the growth, and was clamorous for the removal of it, even if her life was sacrificed in the attempt. It was decided, therefore, to make an effort for her relief. She was given an ounce of brandy, and placed under the influence of chloroform. The cervix was slit with serrated scissors, and the chain écraseur introduced by means of Sim's porte chaine. The tumor was drawn as far as possible, by means of a strong tenaculum, and every effort made to encircle the tumor with the chain, but without success. The tumor was so large, round, and unyielding, while the attenuated cervix and that portion which should have constituted the cervical canal, embraced the tumor so firmly, that it became simply impossible to introduce between these two structures anything so flexible as a porte-chaine. Repeated efforts only brought a flood of hemorrhage, and, having tried to reach the base of attachment by means of large, curved scissors and other appliances, without avail, we abandoned the effort to a future trial.

While trying to introduce the chain, it occurred to me—particularly since the tumor felt precisely like a fœtal head, at full term—that a pair of forceps, constructed like obstetrical forceps, but with larger curve and blades so constructed as to form a toothed and grooved articulation at their extremities, might be readily slipped over the tumor, one at a time, and then used as a torsion forceps, and the tumor twisted from its attachment.

Accordingly, drawings were made, sent to Geo. Tiemann & Co., New York, who produced the instrument illustrated in the accompanying cut.



The entire length of the forceps is twelve inches. Length of blades from pivot, five inches. Inside diameter at greatest curvature, two and one half inches. Width of blades, one inch. The remaining details are sufficiently explained in the illustration.

Just ten days after the last attempt at removal of the tumor, we again chloroformed our patient, introduced one blade of the forceps, then the other, without the slightest difficulty or delay, brought their opposing edges as nearly in apposition as possible, and then rotated the smooth blades laterally, within the uterus, until all resistance was overcome, the blades revolving with the greatest ease and smoothness. Then the tumor was delivered precisely as you would a fœtal head within the grasp of regular obstetrical forceps. Not the slightest hemorrhage followed this delivery, nor did any untoward symptoms arise thereafter, until complete recovery occurred. The tumor measured six inches in its longest diameter, and five inches in its transverse diameter. It proved to be a hard, elastic fibroid.

For all forms of intra uterine tumors, attached at or near the fundus, this forceps offers an opportunity for removal with the greatest ease, safety and expedition.

SOME PECULIARITIES OF TUBERCULOSIS EXPLAINED BY THE PARASITIC NATURE OF THIS DISEASE.

BY F. W. VOGEL, M.D.,

Of Boston, Mass.

Since the careful and extensive researches of Robert Koch have beyond doubt established the parasitic nature of tuberculosis, a good many phenomena of this terrible disease, hitherto unexplained, have become easy to understand.

Tuberculosis, according to Koch, depends upon the presence in the body of numbers of rod-like bacteria, which are found in every case of phthisis, acute miliary tuberculosis, cheesy pneumonia, cheesy bronchitis, fungous arthritis, pleuro-pneumonia of cattle, and sometimes in scrofulous affections, especially enlarged lymph nodes. This slender bacillus, pointed at both ends, the length of which varies from one quarter to one half the diameter of a red blood-corpuscle, is about five times as long as thick, and often shows four to five oval spores, evenly distributed over its entire length. This bacillus, which absorbs methylene-blue but rejects brown aniline dyes, thus differing from all other bacteria known, is a true parasite of the animal body, flourishing only at temperatures furnished by his living abode, and becomes totally inactive at the ordinary temperatures of our climate. Fortunately for mankind it multiplies very slowly, requiring nearly a week to proliferate much under the most favorable conditions, so that it has no footing upon wounds of the outer surface, like other quickly developing organisms, but is washed away by the secretions before it has had a chance to multiply. Even in the sheltered air passages, where it generally makes its first appearance, unless finding its soil prepared by previous inflammatory processes, loss of epithelium, etc., it seems entirely innocuous, being readily removed with the secretions before it has time to take root. When it once has a firm footing, its local extension is still slow, because the bacillus has no movement of its own, and, in order to reach the other parts, it must be carried thither by the lymphoid cells. If, however, the bacilli reach the lymph channels, they are carried greater distances, successively infecting the whole track of a lymph vessel, until stored up in the filter of the nearest lymph node. The matter becomes very serious when numbers of them reach the blood current in the veins, when they become disseminated through numerous internal organs, and acute miliary tuberculosis will be the result.

The anatomy of a tubercle is easily explained now also; a bacillus settles in a tissue, irritates and causes a small-cell infiltration around it; those of these cells nearest the parasite grow up to fibroblasts (epithelioid cells), which, closely pressing upon each other, coalesce and form the giant cell, so often found in the centre of miliary tubercles, harboring one or several bacilli. This giant cell is again surrounded by embryonic cells, some of which are growing up into epithelioid cells. Since no blood vessels form, the centre of the tubercle undergoes fatty degeneration as soon as the growth spreading in the periphery has become numerous enough to take up all the nutriment supplied by the nearest vessels. A number of bacilli appear to die with the cells, which gradually shrink up into a cheesy mass, but others are taken up with particles of detritus by lymphoid cells and are transported into the immediate vicinity, where they begin slowly to proliferate again, giving rise to a fresh tubercle, when the process is repeated over again, adding to the central destruction as well as to the peripheral proliferation. As may be inferred from this, the bacilli are found in greatest numbers where the process is in the act of spreading; where the latter is stationary they are difficult to find.

How do the bacilli enter the system! Koch found that sputa of phthisical patients always contained bacilli; in fact, that the grumous masses so generally present in all vomicæ entirely consisted of agglomerations of these parasites. The drying of a sputum does not rob the bacillus of its life; sputa dried for eight weeks, and injected into guinea pigs, produced acute miliary tuberculosis in every instance. The dry sputum upon the floor is ground into dust; the bacilli, adhering to some particle of the latter, enter the lungs with the air we breathe and are arrested upon some prominent spot of the mucous membrane which lies opposite the air-current, especially the ridges of the alveolar septa.

But there are other channels by which the bacillus of tuberculosis can enter our system. Pleuro pneumonia of cattle being identical with tuberculosis, the bacillus may be introduced into our alimentary canal with the meat or milk of cattle suffering from this disease.

There is one point which might be urged against the conclusiveness of Koch's observations. We mean the hereditary acquisition of consumption. Still this can be explained very easily. Judging from analogy with syphilis, the twin brother of tuberculosis, direct transmission of the disease germ is possible; also that the disease may remain latent, unless the germs are so numerous as to overwhelm the resistance of the

vigorous functions of the young cells of childhood. Furthermore, numbers of them are easily stored away in some lymph-node, where they are kept from doing general mischief for a time. Again, we must keep in mind, that in cases where direct transmission of the disease-germ has not taken place, the direct contagiousness and infectiousness of the bacillus comes into free play, the children being obliged constantly to inhale the infected air of their home, or ingest the parasite with the mother's milk.

The practical results obtained from Koch's valuable paper may be summed up as follows:—

All sputa from phthisical patients are to be disinfected immediately; also the clothing, bedding, etc., before used by other people.

Phthisical mothers must not nurse their infants.

Scrofulous, infiltrated glands ought to be excised.

Meat and milk from cattle which have suffered fron pleuro-pneumonia must not be allowed to enter our system.

Antiseptic treatment, perseveringly and vigorously carried out, is the only rational treatment for consumption. Carbolic acid inhalations through the nasal respirator, local treatment of tubercular ulcers, fungous arthritis, etc., with iodoform, have already given great results, the latter remedy being preferable in places where the drug can remain undisturbed for a longer time.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINICAL LECTURE BY FESSENDEN N. OTIS, M.D.,

Professor of Genito-Urinary Diseases.

Epididymitis.

Gentlemen:—At our former clinic we were considering the last stage of gonorrhœa. I have been hoping for cases to appear as we progress that shall illustrate some of the complications of this disease. You remember the point at which gonorrhœa commences, viz., at the orifice of the urethra, extending, by implication of the healthy mucous membrane, along the urethral canal, developing in intensity as it extends. The pain and discharge are simply associated with an inflammatory condition, which gradually declines in intensity as the disease reaches the deeper portions of the urethra.

As the disease progresses important parts may be involved in the inflammation, and when they are so, we distinguish these accidents as complications of gonorrhœa proper. One of the most important complications is the occurrence of epididymitis, which is an inflammation of the seminal apparatus. You will recollect that the mucous membrane of the urethra commences at the orifice of the urethra, and extends through to the bladder. Now, the inflammation beginning at the meatus, travels along the continuous surface of mucous membrane, and when it reaches the posterior portion it comes in contact with the orifices of the seminal ducts through which the vas deferens opens into the urethral canal.

The vas deferens is the vessel which conveys the seminal fluid from the testes to the urethra, and also along which inflammation travels from the urethra to the testes. It pursues a devious and peculiar course, which it is desirable for you to appreciate, and as we are now more particularly interested in the manner in which inflammation in the urethra finds its way to the testicle, I will take the urethra at its prostatic portion at the openings of the seminal ducts as the starting point.

These ducts opening one on each side of the sinus pocularis, pass backward to the inferior surface of the bladder, along the inner wall of the prostate, at about the junction of the posterior border of that gland, at which point the duct unites with the vesicula seminalis or seminal reservoir, and passing the vesicula to the outer side it passes over the base of the bladder, between it and the rectum, and is deflected outward, and crossing the external illiac vessels reaches the abdominal wall at the external abdominal ring; passing then down through the inguinal canal, it enters the scrotum, descending to join the tail of the epididymis, with the convolutions of which it is continuous until it reaches the secreting lobules in the substance of the testicle.

Now I think you can readily understand how a gonorrhœa, commencing in the urethra and gradually extending back, comes in contact with the seminal duct, which is lined by mucous membrane exactly similar to that of the urethra. There is no reason why this inflammation should not follow along a continuous surface. This accident does occur not infrequently. Occasionally it extends along the canal until it reaches the testicle itself. The inflammation is generally said to be in the testicle, but as it is usually confined to the epididymis and does not reach the seminal lobules, we call it epididymitis.

We have here to-day a case illustrative of this point. John F., of Portugal, aged 36. First time he has had any venereal trouble. Three weeks ago had intercourse, and noticed a discharge from the urethra for the first time about seven or eight days afterward. Had no intercourse in the meantime. Went to an Indian herb doctor, who gave him a prescription to be taken internally, and four days afterward the discharge disappeared. The epididymis of the right testicle began to swell and be painful about four days ago, that is, six days after the discharge disappeared, and still continues so. Present condition: Epididymis much swollen and indurated; cord hard and resistant to touch. Has dragging pains in the testicle.

One of the peculiarities of this difficulty is that it occurs in the later stages of gonorrhœa, when the disease in the urethra is subsiding. One of the peculiarities of all inflammation is that counter-irritation has a tendency to reduce it. In

this case the epididymitis was noticed and felt several days after the discharge had stopped. Usually the discharge ceases a little time before the epididymitis begins. It is probable that the inflammation in the testicle acts as a counter irritant to that in the urethra, and that the inflammatory discharge from the urethral canal is thus arrested.

In the present instance the inflammation has extended by continuity along the vas deferens. Here you see the testicle on the left side, which is perfectly natural; there is no tenderness, nor any engorgement. On the affected side you observe a slight redness. Swelling and redness of the integument is associated, as a rule, with all cases of epididymitis. Here we have the testicle, and lower than and anterior to it a considerable enlargement of the epididymis, which extends up the testicle. The testicle itself is not at all inflamed, and this is the condition in an early stage. You do not always find that an inflamed epididymis can be distinctly separated from the testicle, but you see a common globular swelling apparently including both the testicle and epididymis. When the inflammation reaches the deepest part it is usually transmitted through the cellular tissue in greater or less degree to the tunica vaginalis or the serous sac which contains the testicle.

The testis in fœtal life is situated in the abdomen, and covered anteriorly by peritoneum. Toward the end of fœtal life it descends, and in doing so carries down with it another layer of peritoneum situated in front of the inguinal canal. Thus it takes down into the scrotum a double layer, a membrane doubled on itself so as to form a closed sac. Between these two layers of serous membrane there is naturally a certain limited amount of serous fluid which serves as a lubricating material, which favors the easy movement of the testicle in the scrotum. In a healthy condition there is but a small quantity of this fluid present in the sac, probably a half drachm or so, but on the occurrence of inflammation the amount is greatly increased. The inflammation has extended from the mouths of the seminal ducts to the vas deferens, and from it to the epididymis. When it is intense it is propagated through the cellular tissue into this closed cavity, and an increased quantity of the fluid contained therein is a necessary result. We then have a swelling which obscures the boundaries of the epididymis and the testicle.

In this case we can, without difficulty, feel the line of demarkation between the epididymis and the testicle which would not be the condition had the inflammation been communicated to the serous sac. In that case the swelling would have been larger and fluctuation could be felt distinctly. In some of these cases the scrotal tumor reaches the size of a goose egg.

The symptoms which precede an epididymitis are important. You may always take it for granted that when a gonorrhœa has extended to the posterior portions of the canal there is great danger of its extending into the vas deferens. When the trouble first came on, this man had pain in walking, a little pain in his back, groin, and in the testicle. The ordinary course of the symptoms in cases of this kind is exactly what you would suppose when you know the manner in which the vas deferens passes from urethra to testicle. Pains regularly follow in the urethra, in the perineum, in the back, in the abdomen, in the groin, and in the scrotum. This is the natural course of the symptoms in cases of epididymitis or orchitis. Sometimes you are even enabled to trace the vas deferens by the location of the pains during the passage of the inflammation along its course.

Gonorrhœa is not the only cause of epididymitis, but any source of urethral irritation may set it up. The introduction of a large-size sound may cause the difficulty, and I have frequently found that after the passage of an instrument pain has traversed the whole extent of the passage from the urethra to the testicle. Where I have detected threatenings of an epididymitis following the introduction of a sound, I have been able to fence off the difficulty by suppositories of a quarter of a grain of morphia, introduced at once into the rectum, supporting the testicle in a suspensory bandage, and putting the patient on his back for a day or two.

In cases of this disease always support the testicles. After a gonorrhœa has continued for ten or twelve days it is safest and most prudent to support the testicles with a U. S. Army bandage. With this precaution you are likely to prevent the occurrence of an epididymitis, and will certainly lessen very greatly the danger of its occurrence.

The present condition of this patient is one which calls for simple treatment. With proper care he may be entirely relieved in a short time. He must keep perfectly quiet, and wear a suspensory bandage. I also think a good deal of narcotic fomentations during the acute or painful stage of epididymitis. By their use I think the disease may often be arrested, and always made to run a milder course.

In this case, as I said, I would prescribe absolute rest, and if he suffers any pain a suppository of a quarter of a grain of morphia. For local application let him take equal quantities of cut tobacco and flaxseed and steep them together in a little water; then take an old stocking—this is about as good a method of doing it as any—cut off the heel generously, and sew a piece of tape to each side of it, in order to fasten it up; put the hot fomentation in this, and with it cover the testicles and fasten the tapes around the waist. This fomentation should be renewed several times in the twenty-four hours. The hotter you can keep it the better.

It is always well to clear out the primæ viæ in cases where you find any general febrile reaction, and likewise give a little aconite, and in this way you mitigate the general symptoms. Then, in very acute cases, I have found a nauseant of value. In cases in which the pain and inflammation are very intense, you must put your patient on his back, in bed, and wrapping a towel around the thighs, put the scrotum on it, letting it thus have a support, which affords some relief. Then give a solution of tartar emetic, with epsom salts, until the patient is slightly nauseated.

When at sea I have seen a number of cases in which there was an acute epididymitis, and sim-

ple sea-sickness relieved the inflammatory symptoms very quickly and permanently.

After the immediate active inflammation has ceased, we must have something to stimulate the absorption of the inflammatory products, the serous fluid and plastic material, which form the swelling and enlargement. Iodine is an excellent absorbing agent, and the best form for the purpose here is the ointment of the iodide of lead. After the narcotic fomentations this ointment is very serviceable in reducing the size of the tumor.

When, however, you see a patient suffering intensely with an acute epididymitis, and also observe fluctuation, you have no time to wait for the effect of external remedies. In such a case it is best to pierce the sac of the tunica vaginalis with a hypodermic syringe, and draw off all the fluid contained. No harm can come from this simple operation, and under such circumstances it is always best to do it. First make the integument tense by stretching it with the fingers, and then penetrate quickly with the point of the instrument. When you find fluid in the sac of the tunica vaginalis, which causes pain by making the parts tense and stretching inflamed surfaces, it is always best to remove the fluid and give immediate relief to the patient.

The subsequent results of an epididymitis are of the utmost importance. You know what is the result of inflammation in any part of the body. Plastic material is invariably thrown out, which may organize anywhere, and you see, therefore, how, during such an inflammation as we have been considering, an obstruction may take place in this canal of the vas deferens, at any point over which the inflammation has passed, through the accumulation and organization of the plastic material. If such an obstruction does occur it becomes a barrier to the passage of the spermatozoa to the urethra. If any occlusion exist at any point in the course of the epididymis or vas deferens, the man will be impotent on the side in which it is situated. If the epididymitis is double the occlusion may occur on both sides, and, of course, with such a state of things, complete impotence results, and may possibly become permanent. This, undoubtedly, is a cause of many cases of sterility, following marriage, where the woman is, often unjustly, blamed. A man may have an emission containing all the characteristics of the seminal fluid, but which, nevertheless, is deficient in spermatozoa. There are plenty of men who imagine that there is nothing the matter with them, but that the cause of sterility lies with the wife, when if their emissions should be subjected to an examination, the vivifying principle would be found to be absent.

In these cases you will generally find a lump behind each testicle, a little induration at the point of the epididymis. The proper treatment consists in the use of those remedies that promote the absorption of cicatrical tissue. Give mercurials or iodide of potassium: a quarter of a grain dose of iodide of mercury for three or four weeks will often do great good. Gosselin relates a number of cases where impotence which had existed for many years was cured by this mode of treatment.

Urethral Stricture.

This case is the one we saw last Thursday. The patient was examined and found to have a stricture at the meatus and several bands of stricture further down. His symptoms, which were chiefly neuralgic pains in the thighs, perineum and above the pubis, induced me to believe that his trouble was due to reflex action, experience in many cases having convinced me that this is a common cause of such troubles. Last week I divided the stricture at the meatus, and told you that I was of opinion that all his difficulty was due to that constriction, as it is here rather than at a deeper point, that stricture is likely to occasion reflex difficulties. Since its removal he tells us that the pains that he complained of have left him.

To-day I propose to divide the deeper strictures. Bulbous sound No. 26, as you see, demonstrates stricture in the spongy portion of the canal. Before I have passed the instrument half an inch the stricture is found. This is evidently a very dense one. The bulbous sound passed the constriction with a jerk which any one could recognize, as it escaped the firm grasp of the stricture into the normal urethra beyond.

I now propose to use the dilating urethrotome. This is an instrument which first dilates the stricture and then cuts it. I turn up this screw until the blades of the instrument are separated to correspond with the normal urethral calibre, and then draw a knife through the stricture, which then cuts it completely and entirely through. The important point in the operation is to adapt the knife to the stricture properly dilated, and then made tense and thin; and when that is done judiciously there can but rarely be failure to divide it completely.

The sound, now, as you see, passes easily. I think, however, there is a slight band which still remains, not being completely severed, and as I never feel satisfied until every fibre of stricture is severed, I will again introduce the urethrotome and complete the operation. Now, on testing with the full-eyed bulbous sound, there is seen to be not the slightest obstruction at any point. This is one of the densest strictures that I have ever cut with this instrument. It is now, however, thoroughly divided, and if, as we intend, it is kept from healing by first intention, the cure will in all probability be permanent. I am aware that this doctrine of the radical cure of strictures is not generally accepted, but I hope to convince you of its truth and value before the termination of the session.

Charles Darwin Memorial.

The executive committee of the Darwin Memorial Fund recently held a meeting at the Royal Society's Rooms, Burlington House, where the subscriptions received or promised amounted to over $12,000. A decision was arrived at that a marble statue of the late naturalist should be executed, and a sub-committee was appointed to arrange for this being done. The site chosen for the statue is the large hall of the Natural History Museum, at South Kensington, for permission to place it in which the trustees of the British Museum will be petitioned.

Periscope.

Transfixion of Neck by a Walking-Stick.

In the *Lancet*, Mr. Davies-Colley reports the following curious and interesting case:—

Henry C., aged eighteen, was admitted on March 20th, 1881. Shortly before, he was walking along the side of the curb, carrying in his hand a stick, about as thick as his index-finger, and holding it by the middle, when he slipped and fell upon it. The blunt point entered his neck upon the right side, went through, and projected for about two inches upon the opposite side. With his neck thus transfixed he walked about 250 yards, to a doctor, who pulled the stick out for him, and sent him on to the hospital, after he had plugged up the left opening, from which there was a little bleeding.

On admission, he was a healthy-looking, well-nourished boy, and he had not the appearance of having met with any serious injury. He had not spat any blood, nor vomited, nor had there been any difficulty in breathing. On the right side of the neck there was a wound half an inch long, directed downward and forward, two inches below the tip of the mastoid process, and one inch in front of it. The adjacent skin was slightly abraded. On the left side there was a transverse wound, also half an inch long, directly below, and an inch from, the tip of the mastoid process. A few drops of blood had escaped from the left wound, that of exit, but barely a trace from that upon the right side. He could raise his head from the pillow with little or no pain. There was some pain on swallowing, about the pomum Adami. His voice was not at all affected. The stick was of blackthorn or holly, stripped of the bark, polished and black, with rounded knots upon it. The lower extremity was three-eighths of an inch in diameter, without a ferrule, smooth, and cut transversely, with a somewhat rounded edge. The rest was from half to five-eighths of an inch thick. His wounds were washed with carbolic lotion, and lint soaked in a mixture of oil and carbolic acid applied. He was kept in bed, and had low diet for four days, after which he was allowed to take first fish and then meat. No rise of temperature followed the injury.

March 23d: Still a little pain in swallowing. 24th: Wound on left side healed. 27th: Allowed to get up. 28th: No pain in swallowing. Feels slight pain when the head is forcibly extended. 29th: Right wound healed; there has been no suppuration, only a scanty discharge of bloody serum.

April 6th: Went out, quite well.

Remarks by Mr. Davies-Colley.—From the position of the wounds, and from the subsequent symptoms, it was thought that the stick, after entering the neck in front of the right sterno-mastoid muscle, passed between the vertebral column and the pharynx. In this course it must have been close to the great vessels on the right side of the neck, perhaps between them, near the bifurcation of the common carotid artery. On the other side it probably passed behind the great vessels, and then emerged through the fibres of the sterno-mastoid muscle. The direct line between the wounds would have been through the pharynx, but as there was no spitting nor vomiting of blood, and as the pain in swallowing was slight, it is very unlikely that this cavity was penetrated. In all probability the stick glanced against the vertebræ, and so had its direction altered. It must then have traversed the space behind the pharynx, which, in order to allow of the free movements of swallowing, is very loosely connected with the bodies of the vertebræ. The case is also of interest, as it illustrates the ease with which the vessels slip aside and avoid injury from the penetration of a blunt-pointed instrument.

Significance of Albuminuria.

At a meeting of the Cambridge Medical Society (*Lancet*) Mr. Carter introduced the subject of the Significance of Albuminuria, when not dependent on Bright's disease. He remarked on the frequent difficulty of satisfactorily ascertaining the precise meaning of albuminuria when unattended by kidney disease. Various albuminoid substances were known to occur in the urine, and besides the several forms of albumen, and the globulins, there also sometimes occurred the several ferments, ptyalin, pepsin, and trypsin. The results of various observers went to prove that out of a given number of cases of albuminuria, only about half would be of renal origin, and the remainder would be found to arise from other conditions. In one class of cases it was to be referred to the nervous system —neurotic albuminuria—and like diabetes it was not infrequently found to follow prolonged mental anxiety. The form in which it occurred in young men, the so-called albuminuria of adolescents, had been regarded as neurotic, but Mr. Carter thought it more probable that it was connected with the sexual function; were it of nervous origin it would occur in young women and girls, which it was seldom known to do. It would seem to depend upon some condition peculiar to males. Albuminuria frequently signified mal-assimilation of the albuminoid elements of the food. If the amyloids of the food failed to be normally assimilated, he suggested that a set of conditions occurred of which diabetes was the type; if the assimilation of the albuminoids were faulty, that other conditions arose which were indicated by albuminuria. The late Dr. Parkes had called attention to the condition here referred to, which he called "food albuminuria." In yet another class of cases, albuminuria signified some interference with the circulation of the blood, or some abnormal condition of the blood itself. In those affections of the liver in which it was a symptom, it might depend either on abnormal circulation, in which case serum albumen would appear, or on defective meta-

morphosis of the albuminoids, when it would almost certainly be due to the presence of some other albuminoid. In morbid pulmonary conditions, also, it might indicate either interrupted circulation or defective pulmonary excretion. When it occurred in pregnancy, it appeared that impediment to the venous circulation was commonly the main factor, but there was also an altered quality of the blood itself.

Dr. Bradbury remarked that the subject was one in which he had taken a special interest. With regard to the albuminuria of adolescents, he had in his practice been consulted by many undergraduates affected by it, and had, therefore, unusual opportunities for investigating its cause. In a large proportion of such cases the albumen was only to be found after breakfast, and he had come to the conclusion that it was due to seminal fluid finding its way into the urine in connection with the act of defecation. There could be no doubt as to the existence of many varieties of albuminuria, but it was difficult to determine the different forms. Often it was an accompaniment of indigestion, and sometimes occurred only after the ingestion of certain articles of food, as in one case which had come under his own care, in which it occurred only after the patient had partaken of boiled beef. He had seen cases, also, depending on hepatic derangement due to alcohol or other excess, and had noted the disappearance of the albumen when the hepatic enlargement subsided. Albuminuria with high arterial tension meant, as a rule, commencing Bright's disease; when accompanied by low tension, the probabilities were in favor of there being no renal disease.

Tetanus Neonatorum.

Mr. Sidney Davies reports the following case in the *Medical Times and Gazette*:—

Albert D., aged seven days, was admitted into the Training Hospital about 4 P.M., on April 3. The nurse who brought him stated that he had been quite well, and sucked the breast naturally, till the day before, when his jaws had become firmly closed, so that nothing could be passed between them, and he had a general convulsion, with flexed arms, clenched hands, and difficult breathing. He cried loudly at this time. The mother stated that the first thing she noticed was an attack of wind in the stomach, with spasms of the abdominal muscles.

Both parents were healthy, and had had four other children, all living. Their home was a fair sized cottage, of average cleanliness; the room in which the mother was confined was small. The mother's bed lay immediately under the window, but the nurse stated that she was exposed to no draught during the time of her delivery.

The child was in a state of general muscular spasm, and was crying fairly lustily. It was a very large, well-nourished male child, and had a partial hare-lip. The mouth was partly open, the lower jaw fixed, the brows contracted, eyes screwed up, and whole face drawn. The arms were firmly flexed, and the hands clenched, one thumb being inflexed, the other excluded from the grasp. The legs and toes were also partially flexed. The head was slightly retracted. The breathing was quick and shallow.

A warm bath was ordered, and after being in it about seven minutes the muscles became much relaxed.

About 7.30 P.M. on the same evening the child was seized with another attack of severer spasms. It now cried very feebly, and immersion in a warm bath produced no beneficial effect. The baths were accordingly discontinued. The severe spasm subsided shortly, but a continual state of muscular contraction remained, and exacerbations came on when the child was disturbed, as by feeding. The exacerbations soon occurred without any visible stimulus, and returned, for the greater part of the time it survived, about every half-hour; they lasted from five to twenty minutes. Ordered a grain each of potassium bromide and chloral hydrate in a drachm of water every two hours.

During the night the child lay quiet, apparently asleep, except when the exacerbations came on. Audible cries had ceased, nor did they return.

When seen again in the morning, it lay with both eyes tightly closed, face and mouth drawn equally on both sides, mouth puckered, left pupil larger than right, hands as before. Opening the eye brought on a spasm. Temperature at 10.30 A.M., 103° Fahr. Ordered the chloral to be increased to four grains, and the bromide to two grains, and given every three hours.

In the evening the spasms became more frequent and severe, and during them the child became rather cyanosed. When seen at 11 P.M., the limbs were quite lax, and examination brought on no spasm; but the face was cyanosed. A severe spasm was reported to have occurred at 10 P.M.

The medicine was now discontinued. Three spasms occurred after this, and the child died in a spasm at 1 A.M. Temperature at 9 A.M., 105.7° Fahr.

The child had been fed all along by a spoon, with the mother's milk, drawn off for the purpose. This feeding was performed with some difficulty, but on the whole the child took a fair quantity of nourishment.

Remarks (by Mr. Sidney Davies).—The diagnosis in this case was first made by the friends, for the nurse said, when she brought the child, that it had "lockjaw." Having seen the two cases of tetanus neonatorum which occurred at the East London Children's Hospital last winter, and were reported in the *Medical Times and Gazette*, I immediately thought of that disease; but when the spasms subsided almost completely in a warm bath, I gave up the idea that it was a case of tetanus, and thought it was a simple convulsion. The diagnosis, however, was made sure within a few hours by the following points: The continuous muscular spasm which supervened on the second attack of severe spasms; the fact that a warm bath with mustard did not relieve the spasms; and the absence of sonorous cry. The latter point, though not characteristic of tetanus in adults, was observed in both the above-quoted cases which occurred at Shadwell. The exacerbations were of unusually long duration in this case, lasting from five to twenty min

utes (according to the nurse's statement). The treatment adopted was that which appeared to be partially successful in one of the two aforementioned cases, *i. e.*, large doses of chloral. Certainly a beneficial effect appeared to be produced, and the death of the child—probably from spasm of the glottis—so soon after I last saw it was quite unexpected.

The Scientific Principles of Inhalation.

In the *British Medical Journal*, Dr. Robert J. Lee thus writes:—

The important relation recently shown to exist between septic agents diffused in the atmosphere and certain forms of pulmonary disease, is receiving so much attention that it is well to consider the scientific principles on which it depends. Experiments show that it is possible to diffuse antiseptic agents in the atmosphere by evaporation, and that organic substances may be preserved in such atmosphere without decomposition; or, in other words, that the air may be treated as a fluid, and be charged with antiseptics which prevent bacterial development. Now, when we burn any of the hydrocarbons or gum-resins, we do not volatilize them, and the air is not rendered antiseptic, except to the extent that a certain amount escapes unburnt and is diffused. It follows, from this, that destruction of the antiseptic agent must be avoided. After numerous experiments—and the general results of those made a few years ago were presented at the Cambridge meeting of our Association—it appears that carbolic acid is the only antiseptic, as far as I know, which can be volatilized in a definite and constant manner. This is a most important fact in treatment, and deserving attention. If a solution of 1 part of carbolic acid in 80 of water be distilled under slight pressure, the vapor will contain the same proportion of the acid as the solution during the process of boiling; so that we can obtain vapor of any strength, and diffuse it in the atmosphere. Other antiseptics are either more or less volatile; as, for example, thymol, which comes off very rapidly from the boiling water, as does also benzoic acid; so that they are not convenient for inhaling.

It is also necessary to observe that vaporizing a solution in the form of spray does not volatilize the antiseptic to any great extent, since the dew settles quickly on the nearest surfaces, and does not rise and diffuse itself as the vapor of steam does.

Again, the sprinkling of solutions on clothes does not necessarily secure diffusion of the agent; for, at the ordinary temperature, the agent may not evaporate, but will remain in the texture of the cloth. There are other details which will occur to those who reflect on these matters, and will secure such success as may fairly be expected from the scientific use of atmospheric disinfectants. I trust that I shall be forgiven for egotism in saying that I think the small inhaler exhibited by Maw, Son & Thompson for me, at the International Sanitary Exhibition at the present time, affords the most convenient and scientific means of atmospheric disinfection; and that, until more perfect methods are offered to the profession, I believe it will be found deserving of more general attention than it has yet received.

Intussusception, with Recovery.

In the Boston *Medical and Surgical Journal*, Dr. S. W. Langmaid reports the following interesting case: March 10th he was called to a female child of five months who was the subject of the above accident. The infant had always been well, and had not been particularly constipated.

He saw her on Friday. She had been well until Tuesday night, when she was restless, desiring to nurse often, but rejecting the nipple immediately. The next day she vomited, and cried out at intervals, as if from severe pain. At noon she began to have bloody discharges. The pain and bloody discharges continued until he saw her on Friday. She appeared stupid. The pulse was 120. The abdomen was not distended or tender to pressure. The finger, inserted its whole length in the rectum, encountered a tumor with a central indentation, reminding one, by its shape, of the neck of the uterus.

Dr. Sumner saw her with him two hours later.

A cylindrical tumor existed in the region of the descending colon. The invaginated intestine had come down to the anus, and, holding the child in the inverted position, was seen to be of a chocolate color. The duration of the lesion, forty-eight to sixty hours, and the appearance of the bowel, decided us against any mechanical interference. The condition of the child remained the same, except that the discharges of blood became less frequent and smaller, until Sunday night, when the patient became brighter, nursed, and retained the food. On Monday there were two natural dejections, the tumor had disappeared, and the child was well.

Commenting on this case Dr. Whitney says that in the palliative treatment of intussusception a spontaneous cure is observed in fifty per cent. of the cases. It seems to him that the prognosis must depend very much upon the situation of the intussusception. If it occurs in the small intestines, and especially if the ileo-cæcal valve is invaginated, the chances of spontaneous cure would be less than when the descending colon is the region involved.

Paracentesis Cranii in Hydrocephalus.

In the *Lancet*, Dr. Hugh P. Dunn recommends paracentesis in cases of hydrocephalus, believing that when the operation is properly performed it is not dangerous, but on the contrary, is productive of much good. A small aspirator, of about half an ounce capacity, furnished with a double cock arrangement, is the instrument he uses. The child being held on the nurse's lap, with its head facing the light, the operator marks a point in the situation of the coronal suture about an inch from the longitudinal sinus, and, holding the needle firmly in his right hand, thrusts it into the cranium with its point slightly inclined inward. It is a good plan to first thoroughly cleanse the needle in a solution of carbolic acid. The needle having entered the cranium, the sur-

geon grasps it close to the scalp by the forefinger and thumb of the left hand and steadies the head with the right, and the assistant manipulates the piston of the aspirator. The piston should be slowly withdrawn, and pauses of a few seconds now and again allowed to elapse, in a manner similar to the application of the écraseur. The position of the needle may be altered from time to time, according as the tension on the piston shows that the fluid has diminished. After about half an ounce of fluid has been abstracted, compression of the cranium should be secured. The best way to secure this is to use a piece of india rubber tubing, corresponding in diameter to a quarter-inch gas pipe. The tube, around which some lint may be wrapped or sewed, should be made to encircle the cranium twice, at a level with the occipital protuberance behind and the centre of the forehead in front. As the fluid is gradually withdrawn, the tube is, from time to time, readjusted and tightened. When the operation is completed, the punctured spot is covered with a piece of dry lint and attention directed to compression of the cranium, which can be accomplished by fixing the tube *in situ*, or a capeline bandage of flannel carefully applied.

To sum up, paracentesis cranii is indicated in all cases of acute and chronic hydrocephalus, in which, medicinal treatment having failed, the patient is clearly suffering from increase of the fluid and life is threatened. It is the only means by which life can be prolonged, even if, by its performance, the disease is not arrested. All the fluid which can be obtained should be withdrawn. The operation may have to be repeated, should a re-collection of the fluid be followed by a return of the symptoms which made its previous performance necessary. The risks attending the operation are almost *nil*, if carefully performed.

A Peculiar Skin Eruption During Pregnancy.

Dr. R. J. W. Oswald reports the following interesting case in the *Lancet*:—

Mrs. A., aged forty, the mother of five children, was confined of a healthy male child on March 7th, 1882. She had had no child or miscarriage for eight years and three months previously. When about five months pregnant with this last child, she noticed a squamous eruption appear on the upper third of the forearms, not affecting the flexures of the elbow joints. This eruption gradually became worse, the skin was indurated and raised, and eventually both forearms and hands were affected. Almost concurrently with this the lower limbs showed the same peculiarities, with some variations, however. The enlargement was very great, almost to twice the natural size, accompanied with œdema. The skin was very rough and hard, and appeared similar to "elephantiasis." About two months before the patient was confined, larger bullæ appeared on the lower extremities, but at no time were the upper limbs thus affected. Some of these bullæ burst and formed hard, thickened crusts, from which exuded a thin, glairy fluid. The pain accompanying this affection was very severe, and the patient was unable to go about her household duties for fully three months previous to her confinement. Immediately after the confinement the skin of the forehead, face, neck, and upper part of the chest, which up to that time had been free from blemish, began to be squamous and indurated, and very much thickened, but no bullæ appeared at any time. Both anæsthesia and hyperæsthesia were present. She is now (seven weeks after her confinement) better in some respects, although there are still a few bullæ on the legs, and the skin still shows to a slighter extent the peculiarities just described. The patient is no doubt of a rheumatic diathesis, but whether this, combined with the great changes the system undergoes during pregnancy, has helped to cause this eruption, I cannot say. The only treatment adopted has been absolute rest and the administration of alkalies. Previous to her confinement eight years ago the patient had a similar eruption on the forearms and hands, and the legs and feet were affected also about two months before the confinement. In about three weeks after this the skin was clear again, and the severity of the attack was not nearly to the extent as in the present instance.

Reviews and Book Notices.

BOOK NOTICES.

A Treatise on the Physiological and Therapeutic Action of the Sulphate of Quinine. By Otis Frederick Manson, M.D., etc. Philadelphia: J. B. Lippincott & Co. 1882. Small 8vo. pp. 164. Price $1.00.

A book without either preface, table of contents or index, impresses a reader at first sight unfavorably, as indicative of negligent preparation, or deficient literary skill. This is the case with the work before us, and the impression is not removed by examining the text. It is largely made up of quotations, many of them second-hand, and presents very little original matter. Histories of a few cases are all that the author contributes from his own knowledge. As a compilation from current writings, it will, however, be found to contain many useful facts.

Hints and Remedies for the Treatment of Common Accidents and Diseases. By Dawson W. Turner, D.C.L. 8vo. pp. 106. Cloth. Price 50c.

In the compass of a hundred quite small octavo pages the compiler of this volume gives a vast deal of useful information about matters of every day comfort and hygiene. No one can spend half a dollar better than in buying it. He is too sanguine of success in some of his recommendations, but that is a trifling fault.

What To Do in Cases of Poisoning. By William Murrell, M.D. Second Edition. George S. Davis, Detroit. 1882. 32mo. pp. 96.

This is a "vest pocket" book, and as it is prepared by a competent hand, it may be relied upon as accurate and giving the most recent antidotes.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE MORTALITY IN HEATED TERMS.

The heavy mortality which always attends a "heated term" in our large cities is apt to be attributed, by hasty observers, to the heat directly. But, in fact, a temperature which at its maximum is not equal to that of the normal human body is not unfriendly to health. On the contrary, it is favorable. An eminent English authority on vital statistics has summed up their relation to mortality in the terse sentence, "Waves of heat are waves of life; waves of cold are waves of death."

The same result is seen in comparing the relative populations of countries. The density increases from the absolutely uninhabited poles to the tropics teeming with life in every form.

We must look somewhere else, then, than to the heat alone, to explain why the mortality in New York city, for instance, is, in July, at the rate of an annual average of fifty or sixty per thousand, while in the cooler months it is twenty-five or thirty.

This difference is an artificial one, of man's creating, and is preventable.

We must, indeed, allow that sudden changes, from cold to great heat, act unfavorably, and part of the mortality is fairly attributable to this. Only a small part, however. The great bulk of deaths are unquestionably caused by injurious food and habits of life.

The mortality is greatest among children, whose food is of a character most apt to be spoiled by heat. Pure, sweet milk, scarce at all times, is next to unobtainable in the July heats, in great cities. Fruit of all kinds is abundant, but generally immature or partly decayed. Meat, which is not a diet for hot weather, becomes most easily tainted, and the animals from which it is taken are, at this season, often over-heated or unhealthy. Stimulants of every kind act most hurtfully in great heats, and yet their consumption is actually increased then, the thirst brought on by the actual transudation prompting thereto.

The houses and clothing customary and suitable to moderate weather are both ill adapted to a temperature above 80°. The clothing may easily be thrown aside, but not so the houses. The heated walls maintain the temperature during the night, and sleepless hours wear heavily on the overtaxed, nervous system.

These hints indicate why a "hot spell" is a destructive one in our latitude. Reflection will show that it is so because we will not observe the mode of life, at that period, which the experience of warm countries proves is the suitable one. Even under the unfavorable surroundings of an alley in a city, it is quite possible to be cleanly, temperate, careful about food, and observant of the rules of hygiene. Were this generally so, we should have no such long lists of deaths to witness at such periods.

THE POSITION OF IODOFORM IN THE ANTISEPTIC TREATMENT OF WOUNDS.

The reports of the almost magical results with iodoform as an antiseptic, especially in the treatment of wounds or in operations upon tubercular soil, have been followed quickly by warning voices, which want to banish this antiseptic entirely, on account of its many dangers. The

latter are classed by Küster under the following heads:—

1. *Local Disturbances*:—

(*a*) Iodoform acts as a foreign body, causing partial non-union or fistulous openings, through which the drug may become eliminated as a worm-like pulp.

(*b*) Iodoform may cause a phlegmon, on account of mechanical irritation, probably. The inflammation, often accompanied by fever, shows itself as a diffuse, firm infiltration of the skin, of a slightly purplish color, which is only slowly absorbed.

(*c*) Iodoform gives less protection against erysipelas than carbolic acid.

2. *General Disturbances*:—

(*a*) Disturbances of digestion: food acquires the iodoform taste; the tongue becomes coated; anorexia follows; often diarrhœa supervenes, even with bloody admixture.

(*b*) Iodoform causes fever, especially in excitable patients, which may reach 106° F., while the pulse ranges between 120–160, with a clouded sensorium, a dry and fissured tongue, simulating septicæmia.

(*c*) Iodoform strongly impresses the nerve-centres, in the form of delirium, melancholy, contraction or dilatation of pupils, amblyopia; even mania, has been observed; also loss of sensation (which, however, might have been peripheral).

(*d*) Iodoform may cause death by irritation of the respiratory tract or of the nerve centres.

Since, however, it would be a step backward to throw away a remedy which, especially in scrofulous or tuberculous changes of the joints and bones, has so far surpassed in its beneficial effects all antiseptics hitherto known, it will be well to listen to the voices of Kœnig, Leisrink and others, in whose hands iodoform has shown itself uniformly efficacious, without the appearance of a single untoward symptom. Their success is simply due to their manner of application of this antiseptic. They have given up the application of larger quantities of iodoform in substance, as well as the iodoformed cotton; the former, on account of the danger from absorption; the latter, on account of the imperviousness to the secretions of the wound, often met with. Their aim is to use as little iodoform as possible, and they obtain it with the iodoformed gauze, applied in the following manner:—

(1) Upon all fresh wounds, which are not tuberculous, whether they have been closed by sutures or not, 6x8 layers of iodoform gauzing are placed, and covered by a compress of cotton, gutta-percha paper and a tulle binder.

(2) In all tubercular wounds of bone, joint or soft parts, the walls of the wound are once rubbed over with iodoform, as little in quantity as suffices to reach every part of the wound; (1½–2 drachms have always been found enough). Upon the wound, which has been closed by sutures or left open, the same 6x8 layers of iodoform gauze and compress is laid as upon ordinary wounds. At any further change of the dressing only the gauze and compress are renewed, but not the sprinkling with iodoform. The results in all cases of this class are far superior to those obtained with Lister's method.

(3) In all wounds of cavities (in mouth, nose, vagina, rectum), only iodoformed gauze is used.

Of course, during the operation, and at every change of the dressing, the ordinary antiseptic precautions, with the exception of the spray, have been observed: Cleaning of the field of operation, of the hands of the operator and assistants; rinsing of the wound with a 2 per cent. solution of carbolic acid during, and with a 5 per cent solution at the end of the operation. The latter seems especially indicated, since the disinfecting action of the iodoform is not an immediate one.

A PURER KERATIN.

Organic chemistry is daily increasing this world of wonders. We notice more and more how economical nature is, and with what simple means she often produces great results. Wilhelm Lindvall recently has subjected the egg-shell membrane to a most careful analysis, and published his very interesting researches in the *Upsala Läkarefören Förhandl.*, xvi, 7, p. 546, etc., 1882.

Hammarsten had found that the egg-shell membrane exhibited in all its reactions, and especially by its great resistance to acids in the warm temperature of heated rooms, an intimate relation to elastin, and Hilger has proven the egg-shell membrane to be a substance identical with the elastin prepared from the ligamentum nuchæ, and that even the structure of this membrane denoted a changed elastic tissue. But investigations which Lindvall made under Hammarsten's guidance gave such results that this similarity must be doubted.

An alkaline solution of the egg-shell membrane was made and neutralized, when a very strong development of sulphuretted hydrogen took place, and the addition of acetate of lead caused an undoubted reaction of sulphur, while elastin is perfectly free of sulphur. This result suggested keratin, which, as is well known, is characterized by its great percentage of sulphur.

Prof. Hammarsten then made a careful analysis of the egg-shell membrane, and found that it consisted mainly of a body, the composition of which was 49.78 per cent. C.; 6.64 per cent. H.; 16.43 per cent. N.; 4.25 per cent. S. and 22.89 per cent. O. But this is almost the identical formula of keratin, with the only difference that keratin prepared from other sources contains a higher percentage of carbon. It has long ago been demonstrated that the percentage of carbon in keratin depends upon the source from which the latter is derived. Now the nearest in the percentage of carbon to the keratin of the egg-shell membrane is the one derived from epidermic tissue (skin, hair, wool, etc.). It seems that the easier foreign substances can be eliminated, the less is the percentage of carbon in keratin, and that, therefore, the latter is the purer, the smaller its percentage of carbon. The keratin derived from the egg-shell membrane must actually be considered, therefore, the purest keratin, so far, artificially produced.

Concerning qualitative reactions, the egg-shell membrane possesses also the common qualities of keratin. The membrane has a strong resisting power to caustic alkalies at the usual temperature of a room, and shows the same relation to mineral acids as other tissues rich in keratin.

It seemed interesting to note the results of decomposition of keratin derived from the egg-shell membrane, and Lindvall exposed it, therefore, to the action of caustic alkalies and of mineral acids. At first he thought that by neutralizing an alkaline solution of this keratin a pure peptone was gained as a result, but this could not be fully demonstrated; when, however, the keratin was boiled with sulphuric acid a dark brown solution formed, which on being neutralized with a boiling solution of baryta resulted, after the necessary procedure, in a crystalline precipitate, exhibiting under the microscope the perfectly typical crystals of leucin and tyrosin, the latter in surplus.

As the most important result of these researches Lindvall considers the fact that the keratin, if boiled with an alkaline, probably by hydration, splits into an alkaline albuminate and into peptone, though the latter cannot be freed from impurities and isolated.

Notes and Comments.

Arsenic and the Secretion of Milk.

Dr. Dolam has been the first physician to detect in the milk of a mother who regularly and in medicinal doses (daily dose 0.012 arseniate of potassium) had been taking arsenic for some time, decided trace of this drug. His case is the only one of the kind on record.

The question, if certain medicines, when given to the mother, will be transmitted by the milk, has given rise to many investigations, which so far have led to positive results as regards iodine and iron. That these are transmitted cannot be doubted any more. As concerns mercury the reports vary, and this point is not decided as yet. Beneke and Pauli have demonstrated the presence of salicylic acid in the milk, while the same fact as regards quinine has been denied.

At one of the last meetings of the Berlin Medical Society (Feb. 15, *a. c.*) this subject came up for discussion, and Dr. Ewald declared that of arsenious acid he had not been able to find in the whole literature any other proof for its transmission in the milk than the one quoted above. Ewald then, himself, reported the following case:—

In the spring of last year he was called to a lady, aged 22, who suffered from prosopalgia, of an intermittent type, the pains being very severe, commencing during the night and lasting from two to three hours. During daytime they were absent. These pains had first appeared after confinement, and had then continued for several weeks. As all other remedies (quinine, morphia, chloral, etc.,) had been tried unsuccessfully Ewald concluded, notwithstanding the lady was nursing her child, to use arsenic (solut. Fowl. one part, water two parts, daily dose thirty drops), and he did so with such good result that the pain ceased by the fifth day.

Ewald made several times daily a careful analysis of the milk, but he never found the slightest traces of arsenic. The transmission of the latter in the milk must, therefore, be seriously doubted.

Acute Myelitis with Double-sided Neuritis Optici.

The following case, which Dr. Henry D. Noyes had under his charge and reported in the *Arch. f. Ahkde*, x. 3, p. 331, is in so far of great interest, as the issue of the case was remarkably favorable, ending in an almost complete cure.

A minister of the church, 25 years old, and an habitual and inveterate smoker, but otherwise in perfectly good health, began to suffer first from constipation and then from difficulty in urinating. At the same time he complained of a cold sensation in his lower extremities and could cross one leg over the other with exertion only. First, vision of the right eye, and, about a week later, vision of the left eye also, became very much impaired. In both eyes, but especially in the right, the inner half of the papilla became swollen and hyperæmic. Besides concentric narrowing of the vision there existed also a central defect. Large doses of iodide of potassium were given the patient internally, and the neck and back over the spinal column were cauterized. Gradually the patient reached the enormous dose of about five drachms (18 grams) of iodide of potassium per diem, and this medication was continued for fully one month and a half. The scotoma cleared up totally; two months later both eyes possessed their normal power of vision and a perfectly clear field of vision had been regained. But occasional giddiness, headache, and some difficulty in micturition, notwithstanding a normal composition of the urine excreted, were still present.

In consequence of the favorable issue of the case it must always be an open question, if the diagnosis regarding the seat of the lesion—inflammatory affection of the spinal cord, accompanied by a morbid change confined to the commissure of the optic nerve—was the correct one.

Two Cases of Tumor of the Brain.

Prof. H. Nothnagel has reported (*Wien. Med. Bl.*, 1, 1882) two cases of tumor of the brain, which are highly interesting from a diagnostic point of view.

In the first case Nothnagel diagnosticated a tumor in the corpora quadrigemina, basing his diagnosis upon the fact that these two symptoms, besides others, were present at the same time, an ataxia and double-sided paralysis of the oculo-motorius and of the abducens, in the following form: when looking upward the bulbi hardly moved above the horizontal line—toward the right side a little more but also imperfectly—toward the left side the left bulbous did not move at all, the right imperfectly—downward full motion but the left less than the right. At converging the rectus internus sinister kept behind.

In the second case existed a tumor in the left cerebral hemisphere and Nothnagel had diagnosticated a tumor in the posterior fossa, basing this opinion upon the following group of symptoms: vertigo, staggering in walking and standing, inclination to fall backward, paresis of the favialis, especially the crossed paralysis of the abducens with slight paresis of the extremities, but no perfect paralysis of the latter.

With reference to these cases Nothnagel thinks that he cannot sufficiently insist upon the great caution that should be exercised in the localization of tumors of the brain, as it is impossible, frequently, even to guess at the polypus-like extensions of such tumors.

Athetosis and Vasomotor-neuroses of the Extremities.

Dr. M. Bernhardt, in Berlin (*Sep. Abdr. Arch. f. Psychiatrie Bd.* XII. *H.* 2.) reports a case in which there is at present hemi-athetosis and hemianopsy of the right side. About three years ago, and after a serious illness of several weeks, duration, right-sided paralysis and aphasia developed themselves in the patient, a girl, then seventeen years of age; within a few weeks the aphasia improved, the hemianopsy, which had been existing from the very beginning, continued; the paralysis had given away to incessant and hasty motions of the right hand and the right arm; these choreic motions had also gradually disappeared, and there were left only slow, grasping motions of the fingers, which continued to

the present time, as did also the hemianopsy; the whole right side does not move as easily as the left. This case proves again the correctness of the view formerly expressed by Bernhardt, that athetosis is only a modified (mostly one-sided) chorea, a view which has been accepted now also by Charcot.

Bernhardt reports also two cases of local asphyxia of the extremities, an ailment which must be ascribed to a disturbance in the circulation of the blood in the peripheral parts of the body, but which is without doubt caused by a special morbid condition of the vasomotor centre. The constant current improved one case temporarily and cured the other permanently; quinine in divided doses had been unsuccessful in the first case.

Hypodermic Injections of Caffein.

The *Lancet* says that, owing to its very slight solubility in water, caffein has not hitherto been used hypodermically. M. Tanret has discovered that caffein dissolves readily in solutions of benzoate, cinnamate and salicylate of soda, the double salts being thus formed. Salicylic acid yields the salt most soluble in water. M. Dujardin-Beaumetz has employed these solutions hypodermically, and has ascertained that they do not irritate. Solutions for administration by the mouth may also be readily obtained in this manner.

Iodoform to Mucous Surfaces.

Application of iodoform in diseases of the mucous membranes (B. Fränkel, *Berl. Klin. Wochenschrift*, p. 252), have been found very beneficial in the following chronic affections of the cavities of the nose, pharynx, larynx, lungs, uterus, and of the conjunctival sac:—

(1) Tubercular ulcerations of the larynx are powdered with iodoform once a day. Ulcers appear cleaner, show granulation growth, whole local morbid process retarded, but not cured; subjective symptoms improved.

(2) Phthisis pulmonalis is treated with vapors of iodoform (bottle half filled with water, iodoform thrown in: heating to 190° F. creates iodoform vapors), or inhalation of etheric solution of iodoform (1:60); subjective symptoms, especially cough, improved, fever reduced.

(3) Atrophic retro-nasal catarrh is treated with iodoform powder blown into nostrils or snuffed up, or the iodoform ointment (1:10 vaseline) applied on swab or brush, with excellent results; new life seems to be imparted to the remaining elements of the mucosa, which become more succulent, its epithelium thicker, formation of crusts subsides. Of course, the same treatment for ozæna, with the same splendid results.

(4) Scrofulous rhinitis. Iodoform (1), tannin (2), vaseline (10), is applied with camel's-hair pencil or tampon (the latter on alternate days, into one or the other nostril): the rapidity of cure is astonishing.

(5) Of course, locally, upon all syphilitic affections of these cavities.

[(6) Applications to endometrium in chronic inflammation of this membrane, in powder or with cocoa-butter.

(7) In follicular conjunctivitis (second stage) in minimal quantities directly applied to follicles].

The Antagonism between Strychnia and Opium.

Dr. C. Harrison relates a case in the *Lancet*, which well illustrates the antidotal power of opium over strychnia. A man who had for some time been drinking very hard, mixed up a packet of vermin killer (containing $\frac{3}{4}$ of a grain of strychnia) with about a teaspoonful and a half of laudanum, added some rum and drank the mixture. He was seen about four hours after taking the poison, when he presented evidences of strychnia poisoning. He was given an emetic, which caused him to vomit freely, after which chloral hydrate sufficed to control the spasms. The case is interesting, as, after a poisonous dose of strychnia taken under the most favorable circumstances for absorption, fifty minutes elapsed before any symptoms became manifest, and the man was alive four hours afterward, although he had received no treatment. No doubt a fatal result was prevented and the intensity of the symptoms modified by the laudanum.

Apomorphia as an Expectorant.

We read in *le Journal de Thérapeutique*, that Dr. Beck used apomorphia as an expectorant in sixty-three cases of bronchial catarrh, and in thirty-one of broncho-pneumonia. The bronchial secretion becomes more fluid and the thick secretion common particularly in broncho-pneumonia is ejected with more facility. The prescription for an adult is as follows:—

℞.	Apomorph. chlorhydrat.,	gr. $\frac{3}{4}$
	Ac. chlorhydric. dil.,	♏xv
	Syr. simplicis.,	℥j
	Aquæ,	℥iv. M.

The dose is a tablespoonful every two, three or four hours. A teaspoonful would be the proper dose for children of from three to ten years of age.

Subcutaneous Stretching of the Sciatic Nerve.

The patient (generally a case of locomotor ataxia) is placed in the recumbent position, brought fully under the influence of an anæsthetic, and the femur is then flexed forcibly on the abdomen. It is said that the sciatic nerve is stretched this way around the neck of the femur. Results gained in this manner by Nussbaum in Munich, and by Billroth in Vienna, have been satisfactory. Accidents like luxation or tearing of parts, which were feared by several English writers, have not been met with. Prof. Trombetta, in Messina, claims, in the *Lancet*, the priority in this bloodless operation.

Carbolic Acid in Blood Poisoning.

The French surgeon, Declat, has recently been making some noise about his discovery of the value of hypodermic injections of carbolic acid in blood poisoning. He extends its value to scarlet fever, smallpox, typhoid fever, etc., and declares that the potent little syringe enables him to "laugh at" these diseases. This is the extravagance of enthusiasm. There is some value in the method, but a limited one. Nor was Declat its originator. Four years ago Dr. N. B. Kennedy, of Texas, used and wrote upon the advantages of these injections, and in April, 1881, he read a paper before the Texas Medical Association, in which he claimed priority of all others in its employment.

Special Reports.

NO. IX.—OPHTHALMOLOGY.

BY CHARLES S. TURNBULL, M.D.

Contagious Ophthalmia. On Croup of the Conjunctiva, with Remarks on the Treatment of the Contagious Forms of Conjunctival Inflammation. By H. Knapp, M.D. *Archiv. Ophthal.*, Vol. XI, *No.* 1.

The observation of so-called extreme cases is sometimes required to throw our mind away from the track of familiar views, into new channels of thinking. We then recognize the significance of certain manifestations which we failed to appreciate so long as we noticed them only in low degrees of development. Such an extreme case, from the common group of muco-purulent conjunctivitis, came under my care lately, and forced me to change my opinion of that kind of inflammation, which several authors have described as croupous or membranous conjunctivitis.

Mild cases of this affection, are not infrequent. They begin under the form of acute catarrh or moderate blennorrhœa, but soon are distinguished by the formation of thin, whitish membranes, covering the palpebral portions of the conjunctiva. Under the ordinary treatment of astringents, cold applications and careful cleansing, they get well in from three to six weeks. Having seen so frequently that the membranes had no appreciable influence, either on the gravity or the course of the disease, I did not consider them as an essential feature of the disease, and classified the cases mostly as acute catarrh. Sometimes, when the discharge was more puriform than mucoid, as acute blennorrhœa.

C. S. Bull, in the third American edition of Sœlberg-Wells' text-book, devotes fifteen lines to croupous conjunctivitis, in which he says: "This form has been regarded by some English and Continental authorities as a distinct variety of conjunctivitis, but there seems good reason to doubt this. * * * The treatment consists in stripping off the membrane and cauterizing the surface, as in catarrhal or purulent conjunctivitis."

H. D. Noyes, in his recent treatise on the diseases of the eye (Wood's Standard Medical Library, 1881), devotes a page and a third to "Croupous, or diphtheritic conjunctivitis," (p. 168). Though he describes croup and diphtheria under the same title, he points out the principal distinction between the two forms of exudation, but also regards the croupous membrane as an unessential feature of muco-purulent ophthalmia.

I have changed my opinion on this subject, and concur with Arlt,* Stellwag,† Saemisch,‡ and Wecker,§ who, especially Saemisch, give clear descriptions of the disease, and state that we have to consider croup as a distinct form of conjunctival inflammation. It differs from catarrh, blennorrhœa, and trachoma, by the presence of the characteristic whitish membranes, and from diphtheria, by several points, which I beg leave especially to mention:—

1. In diphtheria the lids are very stiff and hard; it is difficult or impossible to evert them; in croup the lids are supple and soft, and can be easily everted.

2. The diphtheritic lid is unusually hot and painful to the touch, whereas the croupous lid can be handled without much pain.

3. The diphtheritic exudations are continuous

* Text-book, first edition, 1851, p. 85, and his next text-book, Klinische Darstellung der Krankheiten des Auges, 1881, pp. 16–19.

† Text-book, fourth edition, 1870, p. 423.

‡ Graefe-Saemisch's Handbuch, Vol. IV, No. 1, pp. 94–101.

§ Wecker-Landolt. Traité Complet d' Ophthalmol., 1878. Tome I, p. 320.

from the deposit on the surface, through the superficial and deeper layers of the conjunctiva, whereas the croupous exudation is a surface deposit only.

4. The diphtheritic membrane cannot be easily removed, but must be torn off with some force, leaving the subjacent tissue pale and ragged; whereas the croupous membrane can be wiped off as a whole, leaving the subjacent tissue dark red, bleeding, and uneven—finely nodular.

5. The tissue of the diphtheritic lid when cut into is anæmic, and has, in the developed cases, a white, lardaceous appearance, whereas the tissue of the croupous lid is highly congested and soft.

6. The diphtheritic process leads to mortification of the invaded conjunctiva; the croupous process to proliferation, and cauliflower or polypoid excrescences.

7. Diphtheria readily extends from the lids to the bulbar conjunctiva and the cornea, whereas croup is long limited to the lids, and only the severest cases affect the cornea, and seem always to leave the scleral conjunctiva free.

Croupous conjunctivitis begins with the symptoms of an acute catarrh, or mild blennorrhœa, but soon characterizes itself by deposition of whitish membranes on the retrotarsal folds of both lids, extending toward the front of the conjunctiva and the free edge of the lids, as far as the so-called papillary body is found. The membranes consist of coagulated fibrine enclosing lymphoid cells in varying quantities. They may cover the palpebral conjunctiva in patches only, or as a continuous layer of 0.1 mm. to 1.5 mm. in thickness. They can be more or less wiped off, and are quickly reproduced. The surface from which they are detached is dark-red, easily bleeding, uneven, not ulcerous, but finely granular. The lid is moderately swollen, not very sensitive, and can be everted without much difficulty or pain. The discharge is sero-mucous or sero-puriform and moderate. The progress of the disease is marked by the uneven swelling of the papillary body passing over into proliferation, with the production of smaller and larger cauliflower, and polypoid excrescences. The pesudo-membranes cover all the productions, dip into the depressions and crevices of the proliferous conjunctiva, and cannot be detached without lacerating and tearing off portions of the conjunctiva, thus causing effusion of blood, which shows a high degree of coagulability. Croup, in contradistinction to diphtheria, seems never to affect the scleral conjunctiva, and only exceptionally the cornea, there producing ulcers. These ulcers may be superficial, and disappear in a short time, or become more extensive, occupy and destroy the whole cornea. From their whitish aspect and firm, even surface, which is rather raised than depressed, I am inclined to believe that they also are covered with a croupous deposit. Even in that stage they are capable of restitution, leaving an unexpectedly small corneal patch, when compared with their former size and intense milky opacity. They are complicated with consecutive plastic iritis, which may get well without adhesions or papillary obstruction.

Course.—The milder forms of the disease are not infrequent, the severest ones very rare. The characteristic croupous stage seems to follow the catarrhal initial symptoms in a few days; may last for one or several weeks, or from two to six months. When the membranes disappear they get softer, thinner, and brittle; the discharge then is muco-purulent, but still moderate, when compared with genuine blennorrhœa.

The nature of the disease consists in a swelling and proliferation of the papillary body of the conjunctiva, and the formation of fibrinous pseudo-membranes, which are interspersed with lymphoid cells and deposited on the surface, infiltrating the tissues of the lid. Its causes are those of catarrh and blennorrhœa. The disease is contagious and mostly affects both eyes. A constitutional predisposition may, perhaps, be admitted, as the catarrho-blennorrhœic conjunctivitis, which in asylums goes from one inmate to the other, only in a few assumes the croupous character. Croupous conjunctivitis, like pharyngo laryngeal croup, is prevalently a disease of childhood. Some patients have croup of the eye and sore throat simultaneously.

The prognosis, on the whole, is favorable, the disease showing no marked tendency to affect the cornea, and, unlike diphtheria, leading to no gangrene of the parts affected.

As to the treatment, I can only concur with Arlt and Saemisch, in advising to abstain from all kinds of irritant medication as long as the formation of the pseudo-membranes is still active. Uninterrupted application, day and night, of iced compresses to the lids, and careful washing away of the secretion with a soft sponge dipped in a very weak solution of chloride of sodium, chlorate of potash, and the like, should be enforced so long as the inflammation is progressing or at its height. As soon as the swelling decreases and the membranes break off, the cold applications may be limited to an hour every morning, noon and evening, and gradually left off. Weak solutions of nitrate of silver then seem to

be the best remedy, and also mild touching with the sulphate of copper crystal acts beneficially. Saemisch thinks that in a few mild cases he has cut short the progress of the disease by dusting powder of sulphate of quinine on the affected conjunctiva. I have no experience on the use of quinine in this manner, and Saemisch himself warns us not to use it in severer cases, lest the powder, acting as a foreign body, stimulate the inflammation.

I beg leave to take this opportunity for making some remarks on the utility of methodical applications of cold in the severer forms of conjunctivitis, and on the general management of these affections. They are all contagious, yet not in such a manner that an infection through micro-organisms or other substances floating in the air need be feared. Practically, the disease is transmitted only by inoculation. Under proper care, the most virulent gonorrhœal or diphtheritic inflammation of one eye is never transmitted to the fellow eye, even if left open ; a fact of which I have convinced myself by hundreds of cases treated in hospital or private practice. Under proper care? What is proper care? Proper care is two skilled and trusty nurses, the one for the day, the other for the night, who never leave the patient ; further, a rational physician who is not too meddlesome a therapeutist. I speak now of ophthalmia neonatorum, blennorrhœic or gonnorrhœic ophthalmia of the adult; of croupous and of diphtheritic ophthalmia ; also of the acute stage or acute paroxysms of trachoma. The treatment of all of these cases is the same, and amounts to this: So long as the disease is on the increase or at its height, abstinence from all but indifferent local remedies, methodical and uninterrupted application of cold, and careful cleansing ; in the stage of decline, the same treatment in milder form ; in torpid and protracted cases, astringents or mild caustics.

The infant of three days and over, who has blennorrhœa, should have cold applications day and night, by means of thin iced compresses, which cover no more than his burning eyelids. Every fifteen to thirty minutes the lids should be gently separated and the secretion carefully washed out with a fine, soft sponge, dipped in a very weak solution of common salt, chlorate of potash, and the like. Several sponges should always be at hand, kept in an abundance of pure water, so as to keep them perfectly clean. There is no material equal, in softness and efficiency, to fine sponges. To see that they are free from infection is our business, and a very easy business it is, for among all the disinfectants there is one which, unshaken, has stood the test of time: abundance of water. There is no contagion that is not made harmless by sufficient dilution ; contagia can all be drowned. As soon as the little sufferer shows the least tendency to open his eyes, he should be encouraged in his endeavors. Darken the room moderately, so that the influence of bright light does not make him shrink. The opening of the eye is beneficial in two ways : 1st. The movements of the lids beat the corrosive secretion out of the conjunctival sac. 2d. They accelerate the circulation in the affected parts, thus diminishing congestion, stasis, and infiltration. We know that the venous circulation in the extremities of our body is materially favored, I mean mechanically assisted, by muscular action. When a child opens his eyes, the danger is over, only a relapse must not be allowed to occur. The iced applications have to be continued, until the swelling of the lids and the creamy character of the discharge have disappeared. No child need lose its eyes from ophthalmia neonatorum, and no child does, if faithfully treated in the way just described. I unhesitatingly commit myself to this assertion, since the cases over which I had full control terminated favorably, and they count, not by the dozen or hundred, but by the thousand. Other modes of treatment may be good—and there is no doubt that certain eyes escape destruction under all kinds of treatment—but the one pointed out is capable of saving them all, and only in order not to be absolute I admit the restriction of saying, "almost all." But great and incessant care is needed. Prophylactic measures, such as cleansing the vagina before and during delivery, and washing the child's eye with weak, so-called antiseptic solutions, of which nitrate of silver one-tenth to one-fifth per cent. is the best, may be useful, and need only be mentioned. I cannot speak with the same satisfaction of the results of the treatment of gonorrhœic ophthalmia in adults, though the same plan of treatment pursued with the same rigorousness and persistency saves, as far as my experience goes, the great majority of cases. Slitting of the outer commissure, if there be great tension, is beneficial, but can almost always be avoided, since the cold keeps the swelling down. The proposition of Critchett, of London, to divide the upper lid in its centre, in order to save the cornea from destruction, need certainly not be adopted.

What good the application of cold may do in croupous ophthalmia is exemplified by experience.

In diphtheria of the conjunctiva I know of no more important remedy than the energetic and persistent application of cold. I cannot countenance the proposition of Mooren and Berlin, by warm applications to abridge the true diphtheritic stage and lead the process more quickly over into the less dangerous blennorrhœic stage, since I am convinced that nothing is so powerful in diminishing the violence of this dreadful inflammation as cold, and I am afraid that warmth may temporarily increase it and favor destruction of the cornea. I have to differ from the statement of Dr. Noyes and others, that diphtheria of the conjunctiva is a very rare disease in New York. My former assistant, Dr. Born, has taken notes of over seventy well marked cases during the three years that he was house surgeon at the Ophthalmic and Aural Institute. The great majority of those cases, as well as others in my private practice, were cured under the above plan of treatment, persistently carried out. What good the same plan, though less rigorous, may do in severe cases of trachoma, few persons who have not witnessed it would believe. A patient may go for months, and even years, to the dispensary, and then show the usual alternation of better and worse, till a new crop of granulations, or blindness from corneal opacity, compels him to enter the hospital. He is treated with iced compresses several hours during the day, is directed to dip his face into cold water, and is admonished by every moral effort, assisted, if necessary, by mechanical appliances, to keep his eyelids open as much as possible; his lids are touched with the sulphate of copper crystal, and the improvement in most cases is very marked, not to say astonishing. In the course of three or four months I have seen trachomatous lids restored to a healthy condition, with scarcely perceptible cicatrices, and a trachomatous cornea, through which fingers could not be counted, so much clear up that fine type could be read.

What I have said is only a sketch, and if I did not trespass on your time and indulgence, I would fain say more, for I am deeply impressed with the fact that among all questions in ophthalmology—that of cataract, perhaps, excepted—there is none so important as the treatment of contagious ophthalmia."

(To be Continued.)

—M. Gibony has discovered that healthy rabbits become tuberculous if exposed for some time to air expired by animals in a consumptive state; but if this air is charged with carbolic acid it does not produce the disease.

Correspondence.

Cinchonidia as an Antipyretic.

Ed. Med. and Surg. Reporter:—

During the last session of the Alabama State Medical Association, in Mobile, Dr. George A. Ketchum, of Mobile, the leader of the Omnibus discussion, a notable feature of our meetings, presented, as one of the topics for open and general discussion, quinine, which was ably and elaborately treated in its practical bearing by him. The value of cinchonidia was also presented by some of us who had large practical experience in its use, comparatively with quinine.

The question was asked as to its antipyretic value. It will be answered briefly, from one point, by referring to an aggravated case of double pneumonia, in a young negro man, whom I saw on the 17th of May last, the worst case of the worst disease the black man has to contend with, that I have, in more than 26 years' practice, seen recover. Those who have long been accustomed to treating pneumonia in the negro, know its great fatality, much, very much, greater than in the white. Realizing the fact, and inferring the cause, I was readily able to attach great scientific and practical value to the first article that I ever saw which demonstrated, beyond doubt, by many post-mortems, the true cause, which was found to be the greatly smaller lung capacity, proportionately.

This article was by Dr. A. W. McDowell, in the *Practitioner* of September, 1874, and was reprinted in *Compendium* of January, 1875. At different times I have called attention to the fact as corroborating my own views, and credit has been given to me in some elaborate articles, particularly in one by Dr. Alex. Rattray, of San Francisco, in a careful, and certainly, very able article on the "Physiology of Climate, Season, and ordinary Weather Changes." I take this occasion of disavowing the original presentation of the matter. The credit is due to Dr. McDowell, the result of many post-mortems by him at Benton barracks, giving us light, based on anatomical observation, that cannot be gainsayed, and entitles him, justly, to great credit for his thorough work and necessary practical deductions, which give us an infallible guide in the general treatment of our cases.

This man, a laborer on the railroad, had been brought home the day before I saw him, then sick six days. At 9 A.M., on the 17th, I found him with a double pneumonia, stupid, tongue red, disposed to be dry, very deaf, scanty expectoration, and that almost black; pulse 100; temperature 104½°; abdomen slightly tympanitic, not tender nor even the bowels loose. He had, for the next twenty-four hours, 20 drops of turpentine every three hours; occasional small doses of Dover's powder, to control the harrassing cough, with what I rarely ever use in the negro, and especially this late, veratrum, in small doses, every three hours, used simply as a depurant in its action on the kidney.

At 9 A.M., 18th, pulse 108; temperature 105°; respiration very rapid. He was then ordered at once a prescription which was continued as long as any medication was needed.

℞. Potass, iod., gr.lxiv.
Water, f℥j
Sp. lav. co., f℥ iij
Glycerine, q.s. ft. mist., f℥ ij. M.
Sig.—Teaspoonful every four hours.

To each dose was added, when given, twenty drops of turpentine, this to be omitted when the kidneys were affected. Dover's powder mixture, as needed, to control cough. Buttermilk and lemonade freely. At 5 P.M. temperature was 104½°; same general symptoms. In addition to above treatment, was ordered twenty-five grains of cinchonidia, at 4 A.M., 19th inst. At 8 A.M. pulse 100, temperature 101°, respiration 42, tongue red, rather dry. Treatment continued. At 4 A.M., 20th, he had fifteen grains cinchonidia; at 8 A.M., 20th, pulse 88, temperature 100°, respiration 40. At 4 A.M., 21st, he had the same dose of cinchonidia; at 8 A.M. pulse 88, temperature 99¾°, respiration 32. At 4 A.M., 22d, fifteen grains of cinchonidia; at 8 A.M. pulse 76, temperature 99½°. At 4 A.M., 23d, he had fifteen grains of cinchonidia; at 8 A.M. pulse 72, temperature 97¾°, respiration 24. From this time no regular record was kept, and save a complication of rheumatism of the left hip, he went on to steady convalescence, and this morning was able to walk to my gate to inform me of the birth of a son. He did not desire whisky or any stimulant, and had none. Lived for two weeks, or more, exclusively on buttermilk, which he had in large quantities, the alkaline condition of the blood creating a craving for this acid nutritive. This case very plainly answers the question as to the value of cinchonidia as an antipyretic in a disease which sorely tries all our skill and resources. The iodide of potash has its decided and distinct value in the second stage of pneumonia, and I was more particularly led to its use from the fact that typhoid fever has been endemic with us for more than a year, and all diseases tend to low form. I had many years ago heard of the use of iodide of potash in typhoid fever, but the first case that presented itself, in a child of rheumatic antecedents, I was compelled to use it, which I did solely, through the disease till convalescence.

I have treated twenty-three cases in a little more than a year. It is now my general custom, when I cannot conveniently or properly use the treatment suggested by me in the Reporter of April 20th, 1872, and recently advised again at the last session of our State Association, to give in these cases, every four hours, full doses of the syrup of lacto phosphate of lime, and between each dose, to an adult, four grains of iodide of potash dissolved in a teaspoonful of glycerine, to which recently I have also added, with very satisfac tory results, at the suggestion of Dr. Moody, of Pickens county, Alabama, with each dose one or two drops, according to the gravity of the case, of carbolic acid, strong, the crystals. At the time of reading I was greatly impressed with the immense practical value of the article on "The Thermometer and its Use in Medicine" in the Reporter of February 11th, 1882, by Dr. Hugo Engel, which every young physician, and old one too, for that matter, that can get it, should read, and read, and re-read, and fix in the memory.

Recently, in a severe case of typhoid fever in the third week, a black woman, the morning thermometer read 104½°; very sick. The next morning at the same hour it read 100°; too rapid a fall to bode any good. Like the barometer, foretelling the storm, I felt satisfied mischief was coming and that I might look out, with almost unerring certainty, for a hemorrhage from the bowels. To the treatment of iodide of potash and carbolic acid and turpentine in twenty drop doses, which I always add on first approach of dry tongue, I added at once a decided hypodermic of morphine, enjoined perfect quiet, artificial warmth, whisky freely, and ten grains of Dover's powder after every action. Sure enough it came, and came with a rush, in twenty-four hours. The above treatment, with perfect quiet, tided her through this peril, which gave way on the fourth day, and she went on to convalesce. This instructive case is simply added to the above to enforce the necessity of the use of this instrument of precision, without which we must be very often in the dark as to our diagnosis, prognosis and treatment.

Edward H. Sholl, M.D.,

Medical and Surgical Supplies on Railroad Trains.

Ed. Med. and Surg. Reporter.

Your very timely articles in two late numbers of your journal, calling the attention of railroads and the public to the want of proper medical and surgical facilities in case of accidents upon railroad trains, were read with interest.

The subject has come to my notice upon two or three occasions in particular. I am well pleased that you have taken up the consideration of the matter, and trust that your efforts will not cease until some proper action has been taken by the railroad companies, or legislation enacted by the proper law bodies.

Within the past year I have had two very striking illustrations of the importance of having upon railroad trains, and within easy reach, certain medicines and appliances, in case of accident.

While running at quite a speed, along a prominent railroad, the engineer of our train spied a man lying upon the road between the two tracks. The night was dark, and it appeared that a train going in the opposite direction had run into this person, who was walking on the track, on his way home from work. The accident being unperceived by the train hands, the train did not stop. For quite a while, therefore, until our train came along, did the man lie in suffering.

We were not many miles from the city, and the conductor ordered the man to be taken upon the train and conveyed to the depot.

The poor fellow was in terrible agony, and being stout and the car steps high, it was painful to witness the suffering it caused the man in the attempt to place him in the car.

Had the car been supplied with a stretcher, much time and trouble could have been saved, and the man made to feel his wounds less keenly.

Somewhat belated, the train rushed along with considerable speed, and with every motion of the car I could see that the jolting gave the man pain. We were obliged to lay him upon

the bare baggage car floor, with a chair cushion only under his head.

Not a drop of medicine or stimulant was obtainable from the train hands, to relieve pain or to strengthen him until the depot could be reached.

Fortunately, however, I had my hypodermic syringe in my pocket, with which I injected into the man's arm a quarter of a grain of morphia, which gave him some ease.

The other instance was furnished in the case of the baggage master of a train upon a branch of the same road. While leaning out of the baggage car side door, the baggage master was struck by a projection from a bridge, and his skull fractured.

I was summoned from the rear end of the train, and soon hastened to where the man lay.

Not a thing, except ice water, was on hand, excepting, too, the whole-souled willingness of all hands to do what they could; but of what avail was all this without the means of keeping up the heart impulse and strength of the patient, in hopes of eventually saving his life.

I now make it a rule never to travel without my medicine satchel and instruments. On this occasion they were, fortunately, with me. The man was pulseless; his heart beat so feebly as hardly to be heard. Another physician happening on board, and who ably assisted me in every effort, agreed with me that digitalis must be given the man or he would die before the depot was reached.

An injection under the skin was made, of a strong tincture of the drug, which I procured from my satchel, with the hopeful result of bringing back the pulse and the respiration. Thus we worked, with the medicines, etc., I had on hand.

What are doctors, in case of a need of medical aid, without medicines? What are they without the means whereby to perform the necessary preliminary work in case of accident to body or limb? In some cases useless, I say; in others their efforts are crippled.

The two cases I cite are mild: I need but mention the frightful accidents frequently occurring on railroads, far away from hamlet, village or city, with no opportunity for summoning a physician—the nearest one living, perhaps, many miles away—to show that there are times when some such thing is needed as that to which you refer—a full supply of medicines and surgical appliances, so that if doctors be present they have the means at hand for rendering the necessary assistance; or, if physicians are not near, so that the cooler and more intelligent of the train-men or passengers can contribute to the relief of the wounded until medical aid arrives.

To the list contained in your second editorial I would suggest the addition of digitalis and brandy—though no doubt, in ignorant hands, the administration of the latter to excess results in more evil than good.

In the two cases to which I refer the railroad did all they could for the comfort of the patient after reaching the depot; but how much suffering might not be saved if the measure for which you have so warmly pleaded were adopted.

Let the employés upon every railroad—one or all upon each train—be given, as part of their general instruction, some explicit directions concerning the care of the sick or wounded in case of illness or accident. A woman grows sick, and there is nowhere to lay her. In fact, there are, as a rule, *no* accommodations for the sick upon railroad trains.

Corporations governing railroads should, therefore, drill the train hands, as it is proposed to drill the police force, in the means to adopt in case of emergency, with no physician nigh, and set apart some portion of a train for the reception of the sick or injured.

A Case of Poisoning by Brucia.

Ed. Med. and Surg. Reporter:—

I was called in haste, the other day, to see a vigorous middle-aged man, who was suffering from the effects of an excessive dose of medicine taken two hours before, after a meal, prescribed for backache by an old, irregular, occasional practitioner, who claimed to have been at one time a surgeon in the Prussian army. I found the patient with dread pictured in his face, holding by the arms of the chair in which he sat, afraid to move or be touched lest he should fall into convulsions. He had decided symptoms of poisoning by brucia, which are essentially similar to those by strychnia. An emetic was given, and after repeated doses of chloral, an anti-spasmodic, which is thought to be a physiological antidote. Two fifths of a grain of morphia was given hypodermically. In five hours from the taking of the dose (two grains) the convulsive state had largely disappeared. The prescriber claimed that his prescription was copied from a German handbook of popular medicine (published in 1840), and that only a medium dose, according to the book, had been ordered, which I found to be the case. Twelve grains of brucia and half a drachm of conserve of roses, to be made into twenty-four pills, four of which were to be taken twice a day, constituted the prescription. An ounce of ointment, containing twenty grains of veratria, was also ordered.

The proper dose of brucia is not explicitly stated in most of the books. It is placed at not more than half a grain to begin with, by some. It would seem that, as met with, it is an article of very variable constitution.

A moral: The ignorant use of powerful medicines by any one is a bad business.

Thos. S. Sozinskey, M.D.
Philada., July 29.

News and Miscellany.

Registration of Medical Practitioners in Pennsylvania.

The following is an abstract of the report of the Committee on Medical Legislation, read before the Medical Society of Pennsylvania, at its last meeting. Statistics have been collected from all the counties. In most of them registration has been completed. About 500 practitioners have not yet registered. If our Legislature could be

induced to give us a State Board of Health, with authority to supervise registration, much better results might be secured. One hundred and five females have registered.

Carlisle, Pa. R. L. SIBBET, *Chairman.*

Professor Billroth Declines.

In June last Professor v. Langenbeck, who, as well known, has resigned his position as Professor of Surgery at the University of Berlin, wrote to Prof. Billroth, in Vienna, offering him the chair Langenbeck for so many years occupied. Billroth declined. The Royal Society of Physicians in Vienna held a meeting and authorized Professor Dittel to thank Billroth, in the name of his colleagues, for having preferred Vienna to Berlin. To this Prof. Billroth gave the following answer, which we translate from the last number of the *Deutsche Med. Zeitung*:—

"I thank you for your kind expressions, and can only assure you that I did not reflect long about my duty. I am in so many ways intimately attached to Austria and Vienna that I was forced to decline, notwithstanding the brilliant offers, and, I might well say, notwithstanding the great honor and distinction of my teacher selecting me out of all his pupils as his successor; and I must confess that, for a moment, it seemed to me hard to refuse him anything. But I was soon resolved, and stay here with all my heart."

The students of the Vienna University had a torchlight procession in honor of this action of their Professor. The medical world will be sorry, because Billroth would have had a far larger field and greater means for exhibiting his skill in Berlin, which at present is ahead of Vienna.

Effects of Intermarriage.

Some recent researches of Dr. Herrmann show that there is no connection between the number of marriages between blood-relations and the number of instances of cretinism. Marriages between blood-relations appear rather to diminish than to increase the tendency already present of producing cretinism. On the other hand, idiotism may be, and appears to be, produced by such marriages; *e. g.*, Howe records seventeen cases of marriages between blood-relations producing 95 children, of whom 45 were idiots, 12 scrofulous, 1 deaf, and 1 dwarfed.

Items.

—The ethnological museum organized at the "Trocadero," in Paris, possesses 44,000 specimens.

—The cinchona bark plantations in the Island of Jamaica were able to supply, last year, 24,000 pounds of bark.

—It has been found that the current between the poles of an electro-magnet has the property of delaying fermentation and putrefaction.

—The most certain remedy for toothache, and one that is said never to fail, is the following: Saturate a mixture of alcohol and ether with N_2O; a few drops of this applied, on cotton, to the tooth stops the pain immediately.

—The vacancy created by the resignation of Professor Langenbeck from the chair of surgery, and as director of the surgical clinic at the University in Berlin, will probably be filled by the appointment of Professor Volkmann, of Halle. He is, at least, the only one who will be nominated for this important position by the Medical Faculty of the University. Professor Volkmann has especially become known by his "Sammlung Klinischer Vorträge" (collection of clinical lectures,) which have found many readers also on this side of the Atlantic.

DEATHS.

BREHMAN.—Suddenly, on July 20th, 1882, of neuralgia of the heart, Dr. G. Edmund Brehman, of Altoona, Pa.

ELLIOT.—At Peabody, Mass., July 26th, 1882, Dr. Daniel M. Elliot, aged 39 years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

THE INNOVATIONS OF MEDICAL AND SURGICAL PRACTICE.

BY J. M. F. GASTON, M.D.,
Of Campinas, S. Paulo, Brazil.

Theory and practice should harmonize with the facts observed in the different stages of medical progress. Two extremes, alike prejudicial to advancement in science, are notable at present, being an undue regard for the remote past and an anxious craving for novelty on the part of the medical profession. The statistics of bygone days, so far as they have been carefully and judiciously collected, must have an interest for all time, as a basis of comparison with similar data which have been since presented. But when the inferences drawn from past periods by contemporaneous observers without the lights reflected by subsequent investigations are brought to operate upon this era, it must be evident that they cannot contribute materially to the formation of a correct opinion upon any general principles in practice. Facts which are well authenticated must serve as a basis upon which to erect the superstructure in any department of knowledge for after ages, and the only question in this case for investigation is the competency and honesty of the individual observing and recording such data. We must have a voucher for the character of the witness. As we cannot rely upon the reports of those who are not educated and accustomed to the use of the ophthalmoscope or the microscope, as to the characteristics of the structures which are the subjects of examination with these instruments, so it may be held that the untrained exercise of the senses of sight, hearing and touch may be deceptive and not trustworthy, however sincere the observer may be in seeking information, and whatever may be his good faith in communicating these seeming realities. Thus it turns out that many apparent facts of the early history of medicine cannot be accepted as genuine; and the proneness to refer to such observations as testimony of what was learned by our forefathers, shows a want of discrimination between the real and fictitious in clinical experience. Before the discovery of Harvey, for instance, what significance could any accidental counting of the pulsations of the wrist have, in elucidating a febrile or inflammatory disease? and yet it is a very supposable case, that, without recognizing the standard of health or giving the number of beats per minute, such an observer should describe the pulse as slow or frequent; thus, for lack of the requisite knowledge, giving no indications upon which to form an estimate of the real state of the circulation. On the other hand, if, in connection with a casual count of the pulsations, it was noted that it beat eighty, a hundred or a hundred and twenty times in a minute, it would constitute a well defined element in the history of such case. In other words it would be a fact within itself of specific value, and hence worthy of being perpetuated by record.

Although many original special observations are recorded on the part of the pioneers in the vast field of medicine, yet comparatively few of those disjointed data serve to enlighten the medi-

cal philosopher of the present era as to the principles which operate in the performance of the healthy functions, or to assist the pathologist in solving the disturbances of the physical organism. It is, therefore, unprofitable to array the vague conceptions of these early dreamers in the way of precedents for theory or practice in the light of the advancements in medical science; and the quotations of such authorities in standard treatises or in elaborate articles upon any special subject, has no practical end, nor can it serve any purpose for our improvement. Those who desire to display their researches in the lore of Hippocratic medicine remind us of the diligent collector of fossils which interest by their antiquity, yet shed no beam of light upon passing events. They serve simply to illustrate what has been, without giving us any clue to what should be under the changed order of things; and it is surprising that a plea should be made in behalf of any proposed modification upon the effete hypothesis of abandoned vital theories, that should serve as lighthouses to guard us against breakers that may wreck our vessel of progress. The fathers of medicine may be cited as striking instances of absurd doctrines that have been discarded, but never as examples for our imitation or as guides for our advancement in the practical department of medicine.

Turning to the other extreme, of a penchant for novelties in medical development, we are as little benefited by the ignus fatuus light of the present, as by the spectres and ghosts of the past. The true spirit of inquiry which leads to thorough examination of any measure before adopting it in practice, is to a great extent laid aside by the eager disposition to do something new; and while the initiative element accompanied by a wholesome caution is a proper characteristic of true investigation, this feature of innovation upon recognized modes of proceeding without such precautions, is destructive of the entire framework, which has been the gradual growth of experience and induction. The desire for change simply on account of the change from stereotyped forms is unphilosophic and inexpedient, yet many of the younger members of the medical profession at the present day are prone to seize upon recently proposed modes of treating diseases and new processes in the performance of surgery, without due thought as to the matter of improvement. The taste displayed in the selection of elegant preparations is not always accompanied, as it should be, with a consideration of their efficiency, and as these specimens, so nicely put up, are intended to captivate the eye, it often turns out that they are comparatively inert. It is not by any means objectionable that medicines shall be presented in a form that is acceptable to the stomach, yet this must not be done at the sacrifice of energy in its effect upon the general system.

Certain combinations which were formerly in good repute for the attainment of definite results, are now considered as old-fashioned remedies; such as castor oil with spirits of turpentine, jalap and cream of tartar, snakeroot of Virginia and epsom salts, calomel and aloes, ipecacuanha and tartar emetic, digitalis and squills, sarsaparilla and iodide of potash, assafœtida and camphor, acetate of lead and opium, valerian and hartshorne, linseed oil and lime water, ergot and cinnamon, etc., etc. In lieu of these commonplace articles there have been introduced latterly a great many potential substances that have had a larger share of the attention of practitioners, including bromide of potash, bromide of camphor, chloral hydrate, salicylic acid and its salts, carbolic acid, pilocarpine, podophyllin, cundurango, coca, mannita, chian turpentine, iodoform, pancreatine, listerine, duboisine, methylene and a vast collection beside, with the overshadowing foliage of the eucalyptus. We may question the propriety of setting aside remedies of solid worth and tried virtues for others that are more palatable to the patient or more readily manipulated by the druggist, and the wisdom of sacrificing the certain action of medicines to the charm of novelty or the elegance of preparations, as in such articles as the wine of cod liver oil and wine of peptone, in which the original properties are so modified as no longer to secure their proper influence upon the organism. Whoever abandons the reality for the shadow of medication is making a retrograde movement.

The propagation of the influence of medicinal substances to the organism has been undertaken in a variety of channels, yet none have proved so efficient as the hypodermic medication; and while this was adopted long ago with a few articles, it has been so extended of late as to entitle it to a place among the novel improvements of the age. Morphine and quinine have been resorted to for many years by their subcutaneous injection, with the happiest effects; ergotine and pilocarpine have gradually come into general use by the same process; while ether, brandy and aqua ammonia bid fair to maintain their place among the useful applications in this form. But the preëminence given latterly to the use of carbolic acid by subcutaneous injection claims something more than a passing notice. Thus

applied, it effectually arrests erysipelas, and ensures the resolution of glandular tumors, especially in the inguinal region; affording likewise the surest guarantee for the disorganization and removal of hemorrhoidal excrescences. My individual experience sustains all the most favorable claims that have been proffered by different observers of its salutary effects in their several modes of application, and I am prepared to expect yet greater advantages from the extension of its use to other forms of disease. The grandest achievement, however, for hypodermic application, is the very recent employment of the permanganate of potash in this way, as an antidote to snake poison; and the instances have been so multiplied as to leave no doubt of the efficacy of this magnificent discovery.

There has been no period in the history of medicine when the utilitarian element played so conspicuous a part in therapeutics as at present, and the why and the wherefore are swallowed up by the recognition of the fact, in the benefit conferred by any special mode of treatment. Theory is held to be secondary to practical results, in determining upon the acceptability of a proposed measure; and if an accumulated series of experiments satisfy us that in a given combination of symptoms a uniform salutary modification may be secured by a certain routine treatment, it is clearly incumbent upon the physician to adopt it, though the rationale may not be well understood. As a homely illustration—if it is found that hiccough, as it ordinarily occurs, is invariably relieved, by swallowing in measured draughts a glass of sugar and water, who would think it requisite to investigate the philosophy of this simple process before using it. It is, of course, all very well when our theory can go along with our practice, yet experience is, perhaps, the basis of the most valuable resources in our profession, and nothing should be rejected because it does not admit of a rational explanation. Emphatically, the practitioner may say: "For that which I do I allow not; for what I would, that I do not; but what I hate, that I do." When we are assured that thus saith the record of intelligent observation, we must, "nolens volens," put the measure into execution; and the "test of experience" is, for the most part, a correct guide in practice.

That etiology, pathology and therapeutics should be studied and form the basis of all treatment of disease, and that theoretic deduction and induction are important to an intelligent application of the appropriate remedies, does not in any form militate against the utilizing facts analogically, by inference from what has been presented to the recurrence of the same effects under similar circumstances. The relation of cause and effect may be clearly established without understanding the conditions of the sequences; and medical men should not be over nice in exacting a minute comprehension of the mode in which the curative influence of medicines is effected. If a patient suffers from intermittent, and takes quinine in sufficient doses, the disease ceases to appear, yet we may not have a clue to the precise operation of the medicine in securing this result, while reason and common sense tell us that it is rational and even scientific practice.

This empirical treatment of disease is not at all inconsistent with the thorough comprehension of all that is attainable in regard to the theory of medication, and far be it from me to raise any barrier to the investigation of the principles that should regulate the application of means for the correction of the disorders of the animal economy. The noblest aspiration of the scientific physician in his search after truth, should be to fathom the intricacies of diseased action upon the organism, and the hidden modifications of these disorders by medicinal agents, and establish, so far as may be practicable, a rational solution of their relations.

There has, undoubtedly, been important discoveries in the therapeutic appliances during the last quarter of a century; and the experiments of new remedies have added valuable agents to the materia medica, that are as fully entitled to a permanent place in the list of medicines as any which have been in use for a longer period. Yet it must be admitted at the same time that others of a mere fanciful character have had a dazzling reputation without substantial merit.

The fruitless attempts to replace chloroform and sulphuric ether as anæsthetics, illustrates most forcibly the restless seeking for novelties; and the percentage of fatal results from the limited experiences of a few individuals in this wild chase of a will-o-the-wisp, should serve as a caution to the conservative practitioner, and make him contented to let well enough alone.

Reform of abuses in every phase of medical and surgical applications, has been a marked characteristic of the last decade, and perhaps in nothing has it given better fruits than in the adoption of antiseptic processes; yet the admixture of error, even in this, has become apparent very recently, in the discovery that the carbolic acid spray, instead of being advantageous, has been prejudicial in the large majority of cases, if not, indeed, generally, in surgical, and especially in gyneco-

logical operations. This wonder of an hour kept the profession spell bound under the influence of a great name, but the bubble has bursted under the touch of another equally conspicuous.

We find that even the domain of obstetrics has been invaded by the latter-day innovators, and the best established rules for the guidance of the accoucheur are proposed to be set aside; as, for instance, in omitting to use the catheter for evacuating the bladder before applying the forceps, and in the substitution of chloroform, avowedly free from danger in parturition, by the less manageable resort to laughing gas, which should cause a smile of derision by every obstetrician who has occasion to adopt an anæsthetic in these cases. And it has been gravely recommended, in cases of adherent placenta, to produce that most grave of all displacements of the womb, inversion, for the purpose of facilitating the speedy and complete detachment of the adherent mass. It is a notable suggestion, which should be observed in its avoidance by all obstetricians.

In gynecology, which, as now presented, is a grand novelty, there is no calculating at what point the innovations will find a limit, and the opening of a woman's abdomen will perhaps ere long be resorted to with as little ceremony as an examination per vaginam with the speculum was made twenty years ago. Laparotomy has even been practiced as a means of diagnosis, in advance of any positive indication for this procedure as a curative process. Far be it from me to detract from the well earned fame of those who have been prominent in boldly pushing forward improvements in this department, yet it must be admitted that some have overleaped the legitimate bounds of a wise discretion in making human vivisections.

A few years since I was present when an exploratory incision in the linea alba was made by one of the most distinguished gynecologists of the present age, the cavity being opened to verify the nature of the cause for discomfort in the hypogastric region, from which the lady had suffered for some months previously. The bladder, uterus and ovaries being examined, a slight puncture was made in one of the ovaries, from which about a teaspoonful of serous fluid was discharged and the abdomen was closed with silver wire sutures, thus closing an operation to all appearance that had no other result than to enable the surgeon to determine whether any abnormal adhesions of adjacent organs required division. It was the good fortune of the operator that the lady, whose position in society would have attracted criticism, escaped without any serious consequences of this intra-peritoneal exploration. The high reputation of this prominent surgeon might warrant such a proceeding, but it certainly should not be imitated by those of lesser fame.

There seems to have sprung up within ten or fifteen years a sort of monomania for gynecological investigations, extending to the younger men who have entered the ranks of the medical profession latterly, and it is to be apprehended that the attractions of this specialty may seriously interfere with those acquirements which are requisite for the general practitioner. A Spencer Wells, a Keith, a Sims, a Bozeman, and an Emmett, with other notables in this department, by publishing their grand achievements, have turned the heads of the rising generation of medical men toward gynecology. The injurious effect, in a literary collegiate course, of neglecting some text-books and giving exclusive attention to others, is more manifest in the consideration bestowed upon a special branch, to the neglect of the more important topics in the curriculum of the medical student. It is a grand mistake, in entering upon the preliminary departments of medical knowledge, to devote special study to those matters which are supposed to fit the student for a specialty, let that be in whatever direction his inclinations may point. In like manner, it must prove a drawback to proper professional development, for one entering upon practice to limit the area of his services to one isolated class of diseases, as the mutual relations of parts involve so many reciprocal actions and reactions, that a general acquaintance with the disorders of the animal economy is requisite for a full comprehension of any particular disease. There cannot arise the same impediment to a selection of the medical or surgical field of service at the outset, for there is a radical distinction in the qualifications requisite for the one or the other department of duty, and if an individual is conscious of a decided proclivity in either way, there can be no objection to following his own inclination when he enters upon the practical duties of his profession. The rock upon which young men are in danger of foundering is to allow the magnificent attainments of gynecologists to captivate them in such a way as to divert their investigations from other topics essential to success as practitioners.

While many new modes of treatment, medicinal and surgical, have stood the test of practical application for a series of years, others have, after

a brief career, been found wanting in the essentials for adoption in regular practice. Among these, it is matter of great regret that a new process which promised so much at the outset as nerve-stretching, should have been doomed to rest in the tomb of the Capulets, with such pall-bearers as Socin, Langenbeck, Billroth, Weiss, Bergen, Benedict and Althaus.

It is to be hoped that the reunion of divided nerves may not have the same fate, yet the statistics are as yet too limited to furnish any guarantee for its final triumph.

(*To be Continued*).

A NEW FORM OF SPLINT FOR FRACTURE OF THE PATELLA; AND REPORT OF A CASE.

BY T. CURTIS SMITH, M.D.,
Of Aurora, Ind.

It is quite needless to inform any surgeon that the maintenance of the widely separated fragments in apposition, in fracture of the patella, is a desideratum devoutly desired. However easily steady apposition of fragments of bones may be attained in other fractures, this is one where the maintenance of apposition long enough to secure osseous union has persistently defied all skill in all time past. Bony union has been, and is now, the exception and not the rule.

The causes of failure are very apparent, *i. e.*, the traction of the quadriceps extensor muscle drawing the upper fragment upward, and that of the ligamentum patella, if not drawing the lower fragment downward, at least does not hold it up to its proper place.

Now, it is easily noted that the insertion of the quadriceps extensor into the patella is by a fleshy tendon as broad as the superior border of the patella, and that that insertion of this muscle is as thick as the bone itself. So that the upper surface of insertion of this muscle is on a plane with the upper surface of the patella, thus leaving no projection or shoulder against which a splint may be braced and permanently fastened, in order to hold the upper fragment down to its place. Again, the layers of fascia and integument, not always thin, which cover the upper border of the patella, add to the difficulty of pushing down the upper fragment, or of holding it down, very materially.

Again, any considerable pressure by any splint heretofore devised (as far as my limited knowledge goes) has a noted tendency to tilt up the lower margin of the upper fragment, and thus defeat accurate coaptation. The reason for this is plain. Pressure brought on the upper border of the patella must be had by pressing the quadriceps extensor backward at its point of insertion. This necessarily carries the upper border of the bone backward, and therefore tilts the lower edge of the upper fragment forward. The anterior plane of the insertion of the muscle and of the anterior surface of the patella being quite exactly the same, it must necessarily be the case that any considerable pressure at the upper border of the patella must be had at the expense of pressing the tendon backward; but as the insertion is broad, thick and dense, and its reflex contractile response to pressure quite considerable, it becomes at once impossible, or next to impossible, to secure a sufficient projection or shoulder at the superior border, against which to press with a splint in order to bring down and hold down the upper piece of the broken bone.

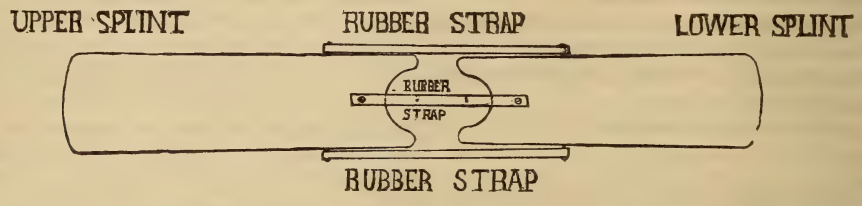
The ligamentum patellæ below offer very similar reasons for inability to hold the lower fragment up, but not to the same extent as the quadriceps extensor above.

To obviate this difficulty, I have devised a splint made to bring pressure to bear on the lateral margins of the bone, where, as will be seen by the shape of the patella, sufficient shoulders may be found against which to press the splints with as great force as may be needed to bring the fragments together. True, the tendons of the vastus internus and vastus externus muscles extend to those lateral margins to a small extent, but not sufficiently to interfere greatly with the mechanism of this splint. The splints may be made of wood, hard rubber or wire. If of wood, take a pine board one inch thick, three or three and a half inches wide. The lower end should be narrowed to a little over two inches. Now groove out one surface deep enough and broad enough to let the tendon of the quadriceps fall into it. Let the groove become gradually more shallow from the lower end upward. Now make a round notch in the lower end, of just such size as that the sides of this notch will fit on the shoulders or lateral projecting margins of the patella, and at the same time be free from pressing on the upper border where the tendon of the quadriceps extensor is inserted. The whole of the pressure will thus be brought against the comparatively projecting sides of this rather double wedge-shaped bone. And no pressure will be had at the upper edge of the bone to cause tilting of the fragments by pressure on the muscular tendon. The lower splint should be made in just the same

way as the upper, only the groove must be deeper and the notch more pointed, to fit the wedge shape of the lower half of the bone. The corners of the board may be rounded off and smoothed up, so as to present a neat and workmanlike appearance, and take away much unneeded bulk and weight.

under the anterior elastic strap and bring them down to their proper place. Or a small strip of whalebone may be bent and slipped through the notches into the grooves after the splint has been applied, and kept there to steady and hold level the fragments.

This splint, by virtue of its reaching well down



There should be screws set into the sides of each splint, two inches or more from the ends, one on each side of each splint, and also one on the top of each splint, in the middle, at about the same distance from the margin of each notch, six in all. To these may be attached elastic rubber straps of sufficient strength to overcome the contractile power of the resisting muscles, and so attached as that they will be tightly stretched when applied. A very moderate continued pressure from these elastic straps will in a few hours overcome all the resisting power of a strong quadriceps muscle, as the muscle will become exhausted and cease to resist the strain brought upon it.

Called to a case of transverse fracture of the patella, how should we apply these splints? First have these splints well and carefully made to fit the patella. Always be sure that the ends of the two splints on each side of the notches do not come quite together when properly applied, and that they fit down on each side of the patella neatly and smoothly. Now secure a long splint for the posterior surface of the limb, reaching from near the gluteal crease to the lower third of the gastrocnemius, or near the heel; pad it well, especially just behind the knee. Also pad the anterior splints above described. Apply the posterior splint and the lower anterior splint, securing them well by a roller. Now tie a strap around the upper end of the long splint and thigh. This steadies the long splint in its whole length. Now bring down the upper fragment of the patella, apply the upper anterior splint and bind it with a roller bandage. If well applied, we believe the edges of the bone will be coapted and retained in place, or will be brought down by the steady pressure of the elastic bands. If now we find the fractured edges of the bone are tilted up we can put a thin or thick pad, as may be needed, over the lateral borders, will also be well adapted to the management of other fractnres of the patella than those that are simply transverse. In a longitudinal fracture the fragments will be more readily held in apposition by it than would the fragments in the more difficult form above named, and for which this splint was especially devised.

The advantages claimed for this splint are (*a*) the groove letting the tendon of the quadriceps extensor in, thus relieving the extensor border of the patella from pressure that is sure to tilt the upper fragment; (*b*) the pressure brought to bear on the free lateral borders of the bone; (*c*) the reasonable certainty of holding the bone in its place; (*d*) and last, but not least, the continued tension of the elastic straps that keep up continued tension and persistently resist the contractions of the quadriceps extensor muscle. Also in longitudinal fractures or in stellated fractures its tendency to hold the fragments in apposition, by virtue of the pressure on the lateral borders.

Case of Transverse Fracture without Separation of Fragments.

In this connection I wish to relate briefly the history of a case of transverse fracture of the patella, occurring in my practice in December, 1872, and which needed no splint whatever. The report of this case was published in the *American Journal of Medical Science*, April, 1873, p. 429.

Early in the month of December, 1872, Mr. Silas Julius, aged fifty-one, a stout, muscular colored man, while walking on the ice, slipped and fell heavily on his right knee. He felt considerable pain and weakness in the joint, but arose and walked to his house, a short distance from where he fell. I saw him the next day and found a transverse fracture of the patella. The fragments were still in close contact; the lower

edge of the upper fragment being tilted up to a noticeable extent, but not down away from its fellow in the least.

The patient was sitting in a chair, limb semi-flexed. When the limb was flexed so as to put the quadriceps on the stretch, the fragments came into exact apposition; but if the limb was extended, the upper fragment would override the lower and project above it the full thickness of the bone. No splint was applied, but the limb left flexed at nearly right angles and ordered to be kept so.

A few days later, Dr. E. C. Fisher, now of Racine, Wis. (a gentleman of ability and professional honor) came to see it with me. We found a disobedient patient. He had been up, walked about, and was sitting up on a chair when we arrived at his house. The leg was slightly flexed. On inspection the upper fragment was found to be actually overriding the lower one.

This condition was so directly the reverse of what we usually find in transverse fracture of the patella, that we examined the case with great care and became entirely satisfied that we were not mistaken, and that the upper fragment was actually overriding the lower one. On flexing the leg, the upper fragment slipped into its proper situation, becoming at once closely coapted to its fellow below. After this the limb was kept constantly flexed until firm osseous union was effected, which was complete in about six weeks, leaving no perceptible deformity. No dressing of any kind was needed to hold the fragments together.

The history and results in this case are directly opposed to what usually obtains in such fractures. We always expect separation of the broken pieces of this bone in transverse fracture, because of the contraction of the quadriceps extensor, and from effusion into the joint.

I was then, and am still, unable to account for the want of the usual separation of fragments in this case, unless it was that the synovial membrane on its under surface, or some slight ligamentous attachment yet unruptured, bound the pieces together. No injury had been inflicted on the quadriceps muscle, nor was there any paralysis affecting any part of the extremity. I have never seen a report of any similar case. Dr. Fisher, who saw the case with me, told me that he related the case to an eminent surgeon in Edinburgh, Scotland, while there visiting the hospitals. This surgeon stated to him that there was one published report of a similar case, but I have not been able to learn where its history may be found.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM GOODELL, M.D.,

Professor of Clinical Gynecology.

Reported by Wm. H. Morrison, M.D.

Prolapse of the Womb, from Hypertrophic Elongation of the Infra-vaginal Cervix—Ovarian Cyst.

Gentlemen:—The case that I shall first bring before you is one of a very interesting disease; interesting principally on account of its rarity. I think this makes the eighth case that I have seen. This is rather a large number for one physician to see. It consists in a hypertrophic elongation of the vaginal cervix, *i. e.*, that portion of the cervix which projects into the vagina. We constantly meet with cases of conical cervix, in which the neck of the womb is a little longer than natural, causing dysmenorrhœa and often sterility, but in the cases of hypertrophic elongation we have a positive growth of the cervix. In this girl the cervix is something like two inches in length.

This girl is twenty-two years old, and has for nine years suffered excruciating pain at her monthly periods. Her physician tells me that he has to give her poisonous doses of morphia before he is able to relieve the pain. The operation that I shall perform to-day will, I think, lessen this pain, but it may be necessary after the parts have united to dilate the cervical canal.

I shall now expose the parts, and as I do so, you see the cervix projecting from the vulva, resembling somewhat the male organ. I pass the sound and get a measurement of four inches. These are the cases which in times gone by were considered hermaphrodites. The cervix was considered to be the penis, and the two sexes were supposed to be combined. The same mistake has also been made in cases of hypertrophy of the clitoris. The neck of the womb is one and a half inches longer than it should be, and projects fully two inches into the vagina. The cause of the dysmenorrhœa is twofold: first this long canal, and secondly the congestion at the menses which blocks up the canal. This is the longest cervix that I have ever met with.

In operating on cases of this kind there is one source of danger. We cannnot tell how far down Douglass' pouch extends. Sometimes it is lower than normal, and in such a case there is danger of opening it. There is some prolapse of the womb and also of the ovaries, due to the weight of the cervix. I now pass a sound into the bladder, to ascertain how low down it comes. I shall amputate a portion of the cervix with a scapula. I catch hold of the upper portion of the neck with a tenaculum, to prevent it from slipping away from me. I now remove about one inch of it by a few strokes of the scalpel. The womb now measures three inches. Before introducing the stitches I shall dilate the canal a little. I shall use the sutures introduced by Hegar, a German gynecologist. The stitches are passed like the spokes of a wheel, from the mucous membrane of the canal to that of the vagina, and in that way union occurs

at the edges, and when cicatricial contraction takes place it is from within outward; that is in the direction in which we wish it, for it will thus tend to draw the os open. You see that the os represents the hub of the wheel, the outer edge of the cervix the rim, and the stitches the spokes. The union here will be slow, for I shall not be able to get the parts in exact apposition, on account of the wound being a circular one. I shall have to put in a great many stitches, and shall probably leave them in two weeks.

You see how low the womb is. Why is that? There are two reasons for it: One is that I have drawn it down, and the other is, that it has been pulled down by the weight of the enlarged cervix. The name of this disease is prolapse of the womb, from hypertrophic elongation of the infra-vaginal (or of the vaginal), portion of the cervix. That is a name which tells the whole story. I have on several occasions shown you cases where there was prolapse of the womb from hypertrophic elongation of the supra-vaginal portion of the cervix. This is the most common form of hypertrophy of the cervix.

I here show you the result. I have introduced fourteen stitches. As I say, the tendency of the cicatricial contraction will be outward, in the direction of the stitches. Although theoretically this is very good, yet practically it is not so good, because there is also some circular contraction, which tends to make the os smaller. I now push the womb high up.

After an operation of this kind you have to look out for secondary hemorrhage, for the parts, being composed of erectile tissue, are very vascular. If hemorrhage should occur, hot water (110°–115°) should be injected. If that fails, alum water should be used. The hot water will usually stop the bleeding, and does not interfere with union by the first intention. Alum does not interfere with union. I never use Monsel's solution in such cases as the present, but where the healing is by granulation, as in cancer, I sometimes employ it.

When I bring her before you, two weeks from to-day, I expect to find the womb and ovaries much higher up. The prolapse has, I think, been one cause of her suffering.

Ovarian Cyst, Probably Malignant.

The next case is one of obscure tumor, which I shall examine before you, and try to arrive at a diagnosis. She is fifty-three years old; has been married sixteen years, and is sterile. It is extraordinary how that word "sterile" enters into the history of these cases. In examining cases of abdominal tumor, fibroid tumor of the womb and cysts of the ovary, we find a very large proportion of the cases in women who are married and sterile or else are virgins, showing that the command given early in the history of the world, to "increase and replenish the earth," is a law of nature, and cannot be violated without causing some lesion.

Last February this lady first noticed a tumor in the left side, and since then she has been losing flesh. This loss of flesh may have a great deal of significance, or it may have very little. It may have been due to the worriment following the discovery of the tumor, or it may have been due to the tumor itself. The history goes on to say that "both broad ligaments are contracted. The fundus of the womb is felt high up, anterior and to the right. Connected to it by the broad ligament is a large, fluctuating mass. It has enlarged considerably during the past month."

The question which I just now asked her was a perfectly proper one, and you notice the indignant tone in which she replied, showing that she is perfectly sound upon that point. The question I asked was this, "Have you tried not to have children?" but you see she has principles on that point. I am very sorry to say that in this country principles on this subject are frequently absent.

There is evidently fluid in this tumor, and it is tender to the touch. Why is it tender? I do not know. The history of ovarian cysts is usually one of freedom from pain. When there are adhesions there may be tenderness. I also notice that the tumor is not mobile of itself. When I move it I also move something to which it is attached, which is the broad ligament. This must be either an ovarian cyst between the two layers of the broad ligament, or else a broad ligament cyst. These are different cysts. Sometimes a cyst of the ovary develops between the two layers of the broad ligament, and we then have an intra-ligamentous ovarian tumor. This tumor is very difficult to remove, because it has no pedicle and has to be enucleated. The cysts of the broad ligament are several. There may be a cyst of the hydatid of Morgagni. I have no doubt that many of you have, in your examinations, found a little body, as large as a pea, filled with a gelatinoid fluid, at the fimbriated extremity of the Fallopian tube, or more correctly, of the ovi-duct. This is the remains of a fœtal structure, and is so common that it has been given the name of the hydatid of Morgagni. We have a second variety of cyst due to enlargement of the tubules of the parovarium. We may have a third variety, what might be called the free lancers of the broad ligament, due to the formation of cyst in the meshes of the connective tissue, not dependent upon any single organ, but occurring here and there in the tissue uniting the two layers of the broad ligament.

We have found, then, in this case, a fluctuating tumor, a lack of mobility and great pain. On percussion, I find resonance all around the tumor. Over the cyst there is some resonance transmitted through the tumor. I shall now examine per vaginam. Her menses stopped in December, 1877—four and a half years ago. The womb is fixed. I lay this down as a good rule for your guidance: when you find a small tumor in the abdominal cavity, connected to the womb by the broad ligament and the womb immovable, the first thing that you should think of is malignant disease. I can, by using considerable force, communicate a sort of movement to the womb, but it gives her pain. The cervix is larger than it should be in a woman fifty-three years old. Although the womb is immovable, I do not feel that mass of exudation posteriorly that I should find if the fixation were due to cellulitis; besides that, it is rare to have cellulitis in a woman so old. Passing the sound, I find that the womb runs to the right. I shall now have her removed.

Whenever you find a womb bound down like this one, with a cyst above it, with close attachments, in a woman fifty-three years old, it is well to consider the disease malignant. I do not feel at all disposed to plunge an aspirator into this cyst. I shall give her anodynes, if it is necessary, and wait developments. As I say, my opinion is that this is malignant disease of some of the annexes of the womb. It may be of the broad ligament, or it may be in the adjacent tissues, or it may be in the womb itself, but I do not think so. I consider an exploratory incision would be unwarrantable under the circumstances.

Rupture of Uterus During Eighth Month of Gestation.

In the St. Louis *Medical and Surgical Journal*, Dr. Walter B. Dorsett records the following case:—

Mrs. A. C. B., colored; aged forty years; nativity, Virginia; occupation, washerwoman. First menstruated at the age of thirteen years, and continued to menstruate regularly all her life, except during her pregnancies. Had given birth to nine healthy children, all of whom were born at full term, and three years apart.

She was a well developed, muscular woman, and had always enjoyed good health. Menses stopped nine months prior to my visit, and she suffered no inconvenience from the condition except from violent movements of the child. She knew she "was in the family way, because she felt just like she did when she was carrying her other children." One evening, about six weeks ago, on coming home very tired, from a hard day's work, sat down to rest, and on jumping very suddenly to catch a little child who was running toward an open fire, she felt a violent pain in her abdomen. She said "it felt like the child stretching out." This was followed by a "giving way" sensation, "then as if a bird was fluttering in her abdomen." Feeling very faint and weak, she immediately went to bed and sent for a physician. The physician soon arrived, and upon examination, found that she was bleeding, and "told her she was in the 'family way,' and that the afterbirth was in front of the child" (he no doubt thought it was a case of placenta prævia threatened with miscarriage); he ordered some medicine to quiet her, then left and did not return.

She said she never felt the child move after this. Her abdomen began to enlarge gradually from this time until I paid my first visit. Though she felt very weak she frequently went about the room. During this time she was always annoyed by a slight vaginal discharge, which was very offensive.

Upon examination per vaginam, the external os could be easily felt; it was soft and patulous, and the neck seemed nearly obliterated. There was a slight moisture in the vagina, due to the presence of bloody mucus, which had a very offensive smell.

The uterus was quite movable and was not adherent to the surrounding tissues. There was a general enlargement of the abdomen, and upon percussion, a very marked dullness, extending from the left iliac region, in an oblique direction, to within two inches of the lower border of the liver, having a general width of about two and one-half inches, could be easily detected. A hard tumor, about four inches in diameter, could be detected in the left iliac region. All other regions of the abdomen were quite tympanitic and very tender to the touch.

The sounds of a fœtal heart, although carefully searched for, could not be heard. She was quite feeble and weak, and the pulse was very slow and easily compressed; heart-sounds somewhat muffled. As she was suffering a great deal of pain, I ordered the solution of morphia continued. I called regularly every day, but could discover no new symptoms, and she grew gradually weak till April 5th, when she died.

April 5th, a few hours after death, I made a post-mortem. The cavity of the abdomen was opened by a succession of careful incisions carried from the lower end of the sternum to the symphysis pubis.

The child's head was found resting upon the intestines, immediately below the stomach, the right arm drawn in a flexed position, with the elbow resting on the anterior surface of the womb; the head, neck and right arm being entirely outside of the cavity of the uterus. A rent in the fundus of the uterus still grasped the child around the left side of the neck and under the right arm. The smell of the escaping gas was so offensive that it was with difficulty that we could proceed. The child, as well as the uterus, was in such a decomposed condition that we could not remove them intact from the abdominal cavity. When the child was lifted up, the right foot was seen protruding through the internal os and engaged in the neck.

This was certainly a most interesting case, and could be none other than a rupture of the uterus during the eighth month of gestation, which did not prove fatal to the mother till the time arrived when she ought to have given birth to a matured child.

The cause of the rupture was very probably due to the violent muscular movements of the child, together with a weakened condition of the uterine walls, superinduced by her jumping up suddenly to catch the little three-year old child.

The child no doubt died shortly after its partial escape into the cavity of the abdomen, or when she felt the "giving way" sensation, and the fluttering sensation was its death struggles.

It was plainly shown by our post-mortem that there had been an effort on the part of the womb to expel its contents, from the fact that the foot was found engaged in the neck, but as the head and arm had been caught in the rent by the contracting fundus, it was impossible for it to accomplish its purpose, and labor ceased. Just at this time would it not have been eminently proper if the physician could have recognized her true condition and performed Cæsarean section, and have at least tried to save the mother's life?

Physiological Activity of Super-oxidized Molecules.

Dr. Charles A. Cameron (*Lancet*) has experimented with the bromates and iodates, and has come to the conclusion that they are more active physiological agents than the corresponding iodides and bromides. The researches of Gamgee, Priestley, Larmuth and others have shown that unsaturated molecules have a higher physiological potency than saturated molecules, especially those containing the same kind of atoms. Carbon monoxide is more poisonous than carbon dioxide; the former has but two of the four bonds of its carbon atom saturated, while in carbon dioxide the four bonds of the carbon atom are saturated by the four bonds of the two oxygen atoms. The pyrophosphates and metaphosphates have unsaturated nuclei and are poisonous, while other phosphates which are saturated compounds are nearly inert, provided their bases are so. The author could not accept as established Rabuteau's theory, that the physiological activity of the elements was proportional to atomic weight.

The author considered that the high physiological activity of the bromates and iodates might be due to the super-oxidized condition of their molecules. The term super-oxidation is no doubt open to objection; but there is no better one to explain the condition of molecules containing more oxygen atoms than are necessary to saturate the bonds of the other atoms present in them. In potassium iodide we have a salt composed of two nomad elements—K—I, and therefore, according to the doctrine of atomicity, it is a saturated compound. When four atoms of oxygen are added to K—I we have six oxygen bonds in excess of the number requisite to saturate the iodine and potassium.

More than a year ago he introduced two new compounds—namely, iodate of quinine and bromate of quinine. They have been so largely prescribed in Dublin that one firm alone, Messrs. Graham & Co., have sold more than a cwt. of the iodate, in the form of a granulated effervescing compound, each drachm of which contains two grains of iodate of quinine (a dose). The iodate has been found a valuable remedy in sciatica, severe articular pain which had resisted the action of the drugs which generally afford relief in rheumatic and gouty affections, malarious enlargement of the spleen, sluggish forms of pul monary congestion, and in secondary syphilitic disease.

Iodate of quinine is prepared by neutralizing freshly precipitated quinine hydrate, with a solution of iodic acid in eight parts of water. The temperature may be raised to 100° F. Dried at a temperature of 100°, it loses no further water by being kept in vacuo over sulphuric acid. It therefore, prepared in this way, contains no water combined. The mean of several analyses showed that it contained 22 per cent. of iodine; it is, therefore, composed of a molecule of iodic acid and one of quinine: $C_{20}H_{24}O_2N_2HIO_3$. The theoretical proportion of iodine would be 22.92 per cent.; but the salt was faintly alkaline, showing that there was a trace of free quinine. The iodate dissolves in 700 parts of water, and is freely soluble in spirit of wine, less so in ether and alcohol. Hydrochloric, acetic, and most other acids dissolve it, forming colorless solutions. If strong sulphuric acid be allowed to drop on quinine bromate, a detonation occurs, a puff of black smoke is given off, and the compound is completely decomposed. On quinine iodate the strongest sulphuric acid produces merely a change from a white to a very light yellow color; and the addition of water forms a colorless solution. At 100° Centigrade, quinine iodate undergoes slight decomposition.

A brief reference to an iodate of quinine is made by Serullas, but of bromate of quinine no account could be found in the books or journals. It may be prepared by precipitating barium bromate by sulphate of quinine, and evaporating the solution separated from the barium sulphate, also by neutralizing bromic acid solution with quinine. It occurs in milky, minute needles, very soluble in water, spirit of wine, and dilute acids, except nitric acid. It is fully as active in its physiological effects as the iodate. It may be prescribed as a mixture, in pills, or in the granular effervescing mixture of the Pharmacopœia. It is soluble in 250 parts of water. Soon after the administration of the iodate of quinine, iodic and hydriodic acids appear in the urine. The quinine also appears, but arrives somewhat later.

The Iodoform Dressing in Vienna.

Dr. Roswell Park writes a very interesting communication on this subject to the *Annals of Anatomy and Surgery*. He says that Vienna was the scene of the first trials of iodoform, and Moosetig-Moorhof makes the statement that he has now treated about 7000 cases with the drug since he began to use it. These were cases of all grades of severity. In all this large number he had seen no case which exhibited any of the characteristic signs of the so-called iodoform intoxication. But Dr. Park adds that since this report, it is currently rumored that he nearly lost one case from this cause. His method of using it is based on a principle, and differs from that employed by most men who use it freely. He holds that since carbolic acid is eliminated by the kidneys, the elimination of iodoform by the same emunctories is prevented, if the carbolized spray or irrigations of carbolized water are used during, or even before the operation. He, therefore, uses nothing but clean water during the opera tion, and then applies iodoform, with full confidence that whatever amount may be absorbed can be readily removed by the kidneys. In the general hospital, Billroth, Albert, Dittel and Weinlecher have all settled down into about the same routine in using it. The part to be op-

erated upon is scrubbed with soap and carbolized water, and then carefully carbolized again. The operation is then performed. All the instruments and sponges are laid in carbolized water, and before dressing the wound is thoroughly irrigated with a 3 per cent. solution. It is then dressed with iodoform gauze. If advisable, the wound may be dusted with iodoform powder; in sub-periosteal amputations, it is dusted in many cases under the periosteum; in osteo plastic resections, between the ends of the bones, and after extirpation of tumors, many would sprinkle it upon the inner surface of the flaps. Under the influence of iodoform, there is much less suppuration, and whatever discharge takes place is more of the nature of a serous exudate.

An absolute indication for change of dressing is an elevation of temperature after it has been for several hours or days normal. Relative indications for the same are pain, and burning and itching in the part.

Iodoform ranks ahead of carbolic acid as an antiseptic, and it, undoubtedly, promotes absorption more rapidly than any other medicinal agent. For this reason it is largely used by syphilologists and dermatologists in Vienna, for hastening the subsidence of buboes and of scrofulous adenoid enlargements. They inject it in ethereal solutions. There is much room for doubting the anti-tuberculous properties which its introducer claimed for it. It undoubtedly promotes healthy granulation, but that it can change a tuberculous into a healthy process in any other way is hardly credible. Some systems are very tolerant of this drug. Gussenbauer, of Prague, after resecting an ankle, stuffed over eight ounces of iodoform into the wound without any bad result.

Whether iodoform thus filled into an open wound is any better than boracic acid is an open question. But there can be no doubt but that iodoform should become in America, as it is here, *the* antiseptic of the present and immediate future, for general use, until something better offers. As at present used here, in small quantities, it has caused no real trouble. Bearing in mind that no case has been reported of serious trouble following the use of not more than one hundred and fifty grains at one time, we may proceed, intelligently and fearlessly, though withal watchfully, to the most thorough and radical operations, confident that by the judicious use of this agent in our dressings we can accomplish all that surgical art can achieve, and at much less expense of money, time and labor, or pains; and even do all this better than it was done three years ago by the sole aid of carbolic acid. Surely the time is past when an American surgeon can be condemned for not using the spray.

Pemphigus Vulgaris.

June 21st of this year the Berlin Medical Society had a very interesting meeting, a report of which we find in the *Deutsche Med. Zeitung*, of June 29th. Dr. Schœler presented a case of pemphigus vulgaris.

The patient, a girl, eight years old, well developed, and having enjoyed up to that time very good health, was taken sick in August of last year. She complained of not feeling well, and had mild fever. Around the mouth and the lips slight swelling and redness appeared. A few days later vesicles of the size of a pea, and filled to tension with a clear, watery fluid, became visible. The same redness and swelling made their appearance on the elbows, the knees and ankles, and spread from there over the extremities and the trunk. The face was not excepted, neither were the eyelids. Whenever the vesicles had existed a few hours or a day, they either dried up and formed scabs or they burst, and the watery fluid oozed out. During the further progress of the disease this fluid assumed a dirty appearance, and some of the vesicles were, from the beginning, filled with a bloody serum. After a few weeks, and when the fever had ceased, the vesicles became continuously larger; at last they were of the size of a hen's egg, and appeared in such rapid succession that the whole back looked like a raw surface. After the discharge of their contents, or after the falling off of the scabs, the vesicles left no cicatrices, but red spots persisted for a long time, and on the sites of the vesicles filled with bloody serum pigmentary changes took place. Not only the skin, but the scalp and the mucous membranes also became gradually the seat of this eruption. Vesicles, or rather bullæ, formed in the mouth, in the rectum and in the vagina. Micturition and defecation were painful. But the general health of the child did not seem to suffer; nay, notwithstanding the little patient had to be confined to her bed from August to January of this year, she increased her weight by four pounds; which is the more remarkable as the child suffered from three to six times daily from epistaxis. During January a remission took place; the bullæ again became vesicles, and these smaller and smaller, and appeared at longer intervals; and for the last eight weeks only one little vesicle of the size of a split pea makes its appearance every few days. During the long illness her hair fell out in great quantity, and she lost her nails. And what is a rare occurrence, on the place of the old bullæ in the face and over the upper part of the body an immense number of miliary papules have developed.

About a week ago the patient had to be attended for an eye affection. The vesicles on the lids had also spread further and attacked the mucous membrane of the eye. During her whole illness the girl had, on account of the secretion and of the photophobia, not been able in the mornings to open her eyelids. Only a few days ago her mother had observed on the left eye a membrane stretched over it, from the canthus internus to the middle of the organ. On ectropiosing the eyelids a prominent cicatrix is observed on the left upper mucous membrane of the lid. The rest of the mucous membrane is shrunk up, and has lost its natural gloss. The right eye exhibits a similar picture. On the cornea one notes fine circular spots. The whole process may be compared to the appearance of conjunctivæ which for years have been cauterized most energetically.

The prognosis of this *pemphigus vulgaris* is rather doubtful, but considering the youth of the

patient and the fact of the vesicles having become so much smaller, fewer and rarer, it may be more favorable than is usually the case. Medical literature has only very few such cases on record.

Regarding the treatment, the eye physician, after cutting through the anchyloblepharon, has continued the measures adopted by the attending physician, viz.: Fowler's solution internally and aq. calcis externally.

Treatment of Fungous Arthritis.

The French pathologists apply the designation fungous arthritis to that form of chronic synovitis or arthritis in which the synovial membrane becomes white and sodden and the articular cartilages more or less eroded and disorganized. At a recent meeting of the Société de Chirurgie, M. Marc Sée presented a young girl who had tuberculous or fungous arthritis of both knee joints. After considerable treatment M. Sée decided to follow the practice of certain German surgeons who recommend injections containing iodoform for the destruction of tuberculous products in inflamed joints. He injected fifteen minims of a 20 per cent. solution of iodoform in ether into the left knee, which was most affected. The next day the knee was swollen, red and painful, but after a few days of perfect repose of the joint these symptoms disappeared, and after fifteen days there was notable amelioration in the condition of the joint. A second injection was made into the joint, with gratifying results, for the lateral immobility has at present disappeared, and the patient can use the limb in walking.

In the discussion which followed M. Desprès remarked that he had made iodinized injection into joints in three cases; in one, of dry arthritis, the patient succumbing two years later to a cardiac affection, when the joint was found filled with pus, whether of recent formation or not he was unable to determine. In the two other cases excellent results were obtained.

M. Verneuil said that at a therapeutic point of view, distinction should be made between fungous masses of recent origin and those of old date. In the second place, at an anatomical point, these fungous masses may, according to M. Verneuil, be divided into three different varieties: 1st. Those which succeed to chronic rheumatic arthritis. 2d. Those which contain tuberculous follicles, constituting tuberculous synovitis. 3d. Those which are symptomatic of an adjacent bone disease. In practice, this distinction of varieties is of capital importance, for on it must be founded the course of treatment to follow.

Where the fungous masses are of tuberculous origin, cure cannot be obtained by ordinary therapeutic means; resection often proves insufficient, for there is more or less rapid relapse; in such cases it is very often found necessary to have recourse to radical measures, amputation often proving the only resource. Where, however, the fungous masses are of rheumatic origin, immobility, with iodinized injections, succeed very well. The treatment is long, and anchylosis generally the result; however, in some cases, the movements are regained.

Finally, when disease of adjacent bone is the cause, it will generally suffice to resect the diseased bone, and the fungous masses will disappear.

It has been recommended to excise and remove the entire synovial membrane, but this operation is very difficult, and what is more, unnecessary, for removal of the diseased bone generally induces disappearance of the fungous masses. So, then, according to M. Verneuil, the rules for practice in such cases would be as follows: 1st. No active intervention in fungous arthritis of rheumatic origin. 2d. Resection and, unfortunately too often, amputation, in cases of tuberculous nature.

Ringworm of the Scalp.

In the *British Medical Journal*, Dr. John Cavafy recommends the following procedure for the cure of ringworm of the scalp:—

Thinking that the accumulation of sebaceous matter and epithelial debris in all probability prevents the penetration of remedies into the follicles, which are further blocked by the swollen, diseased hairs, and that it should be our object to bring any parasiticide into contact with the most deeply seated fungus, it occurred to me that we might attain this end by the employment of a parasiticide held in solution in a fluid which should also dissolve fatty matters. It certainly seemed to me desirable to exclude fatty and oleaginous materials from the remedy, and to apply this in solution, *i. e.*, the minutest form of subdivision. Accordingly, I determined to employ a solution of boracic acid, twenty grains in an ounce of spirit, to which a drachm of ether was added; and directed this lotion to be forcibly rubbed into the affected parts of the scalp, with a rag or moderately stiff brush, three times daily, the whole head being ordered to be washed every morning with plenty of hot water and soap.

The result of this treatment in severe chronic uninflamed cases is certainly excellent, when it is faithfully carried out. The frosted, scaly aspect of the diseased patches is soon replaced by healthy-looking scalp; the broken and twisted hairs appear to be removed, and a healthy growth makes its appearance. When the scalp is seen shortly after the application of the remedy, it is found to be shining, owing to the presence of a fine glaze. This, I presume, consists of dissolved sebaceous matter mixed with boracic acid, deposited in a thin film after evaporation of the solvent; and for this reason I think its removal by soap and water is a necessary adjunct to the treatment. This would, perhaps, be best effected by alkaline spirit of soft soap, which, however, I have not used.

Now, will this treatment suffice to cure chronic uninflamed ringworm? I should hesitate to say. I have certainly seen many cases in which the disease appears to have been entirely removed; but (there is always a "but" in the treatment of ringworm) I must admit the possibility of a diseased stump or two having remained. I find it an extremely difficult matter to be quite certain that every hair is healthy on a scalp which has

once been affected with ringworm, and in this I believe my experience is not singular. I have had cases which seemed cured brought back to me on a future occasion with distinct ringworm; and it is, no doubt, possible that this may have started from an old, undetected, excessively minute focus. But, with our very imperfect means of observation of hospital out patients, it seems equally possible that such cases may be due to reinfection, either from other children in the same family or from a new source.

I may say, in conclusion, that Professor Kaposi (*Hautkrankheiten*, ed. i, p. 740) recommends, among other remedies, the application of alcoholic and ethereal solutions of carbolic and salicylic acids. These would, no doubt, do very well; but the entire absence of any irritation by the use of boracic acid seems to me in its favor, while its efficacy as a parasiticide is unquestionable. The remedy may be, no doubt, varied in different cases; but, if our object is that it should penetrate into the hair follicles, I certainly think that it should be employed in solution, and forcibly rubbed in, and that the use of an oily or fatty vehicle is to be deprecated.

Static Electricity as a Therapeutic Agent.

At a recent meeting of the New York Academy of Medicine (*Boston Med. and Surg. Jour.*) Dr. J. Knight read a paper on this subject. The author stated that he had had a personal experience with static electricity, of fifty years. He related a case of wrist-drop which he had cured in two weeks by its application from the shoulder to the phalanges. Very frequently, on account of unfavorable atmospheric conditions, he had been compelled to resort to dynamic electricity as a substitute. But he has now obtained an instrument (Holt's induction machine) by which statical electricity can be generated in any quantity at almost any season of the year. Statical electricity differs in its effects from dynamic, and is more widely applicable as a therapeutic agent. It is not only an excitant but a sedative as well, while dynamic electricity acts merely as an excitant. He believes that static electricity coöperates with vitality, and this is always to be regarded as the central idea in connection with electricity. In the second place, it has great reactive power. This is so intense that the nervous system will respond to electricity when all other stimulants have failed to excite it. It is likewise an alterant, changing the action of an organ by improving its general tone, and it promotes nutrition. As a general rule it is better to have the current feeble rather than strong, and it is advisable to repeat it at frequent intervals, applying it at each sitting for a considerable time continuously. Golding Bird stated in 1846 that static electricity ought not to be used in confirmed organic trouble, as in such cases it was likely to bring on fatal apoplexy. Dr. Knight does not hesitate to use it in such cases in his own practice, but he believes that venesection, in addition, is essential, to avoid the dangers referred to. He has found it especially useful in various forms of paralysis of the hand and forearm, and in not a single case of this kind has it failed to afford relief. In rheumatic paralysis or wasting of muscles he has found it very useful, and in only two out of ten such cases has it failed in his hands. He places the patient on an insulated stool and applies the electricity from the upper cervical vertebræ to the extremities, drawit off by means of metallic points. In conclusion, he gives a warning as to the abuse of the agent, and says that he has seen patients who have been irrecoverably injured by this as well as by dynamic electricity. If a tendency to apoplexy is noticed during its employment, hydragogue cathartics will generally suffice to remove it; but, as already mentioned, it will be necessary in some cases to resort to venesection. Dr. Dana had obtained excellent results in two cases of constipation, where galvanism and other agents had failed. Dr. William Morton is of opinion that the electricity should be used in large quantity, and should be applied, as far as possible, directly to the spot affected, as he does not believe it to have any general effect upon the system at large. He considers it to be almost a specific in hysteria. Many cases of spinal anæmia, with emotional disturbances, hemi-anæsthesia and other similar manifestations, will yield beautifully to free applications of static electricity to the spine. Dr. Rockwell considers static electricity very valuable, but does not believe it to possess more merit than some of the other forms. In a number of instances he has noticed that after a time the improvement which had at first taken place under the use of various forms of electricity ceased, and in these cases the static form can be resorted to with very good results.

An Apparatus for the Administration of Ether.

Dr. J. C. Hutchinson recently presented to the Medical Society of the County of Kings (*Proceedings of the Society*) an ether inhaler, which he describes as follows:—

A tin tube for holding a sponge for the ether, three and a quarter inches long and two and a quarter inches in diameter; one end is left open, to be covered by a muslin bag, the other is closed, with the exception of an opening at its upper part, one inch in diameter, into which is inverted a tube for attaching a rubber hood. This tube projects backward three-fourths of an inch, and is then carried downward, at a right angle, to a level with the lower margin of the sponge tube. This arrangement prevents the liquid ether from running down upon the patient's face or mouth. There is an opening in the centre of the top of the large tube, one inch in diameter, having a neck half an inch long, which is closed by a cork; through this opening the ether is poured upon the sponge without removing the mask from the patient's face. A rubber hood, such as is used in giving nitrous oxide gas, fits accurately over the mouth and nose, and may be so adapted to any face as to completely exclude the air. The neck of a muslin bag, pear-shaped, eleven inches long, and eight or nine inches wide at its widest part, fits closely over the open end of the sponge tube, and has a slit an inch and a half long at its mouth, to the corners of which tapes are attached, for the purpose of tying it tightly around the

opening through which the ether is poured, so as to prevent the entrance of air at this place. The bag should be made of close material, and when it is wet with water, it is impervious, or nearly so, to air or ether vapor.

Mode of Using the Inhaler.—When about to be used, the large tube is filled with a piece of coarse sponge, of proper size and shape, which has been previously wet with water and thoroughly squeezed. The bag is then wet and squeezed, so that it does not drip, and secured over the mouth of the tube. The sponge will hold two ounces of ether, which should be poured upon it through the opening on the top of the tube containing the sponge. In most operations the first charge of ether is all that is required, and in many, half the quantity mentioned is quite sufficient. The rubber hood is applied accurately over the mouth and nose, but the opening through which the anæsthetic is poured is left uncorked until tolerance or partial anæsthesia of the mucous membrane of the air passages is established, as indicated by deep inspirations. Free dilution of the ether vapor with atmospheric air when its administration is first begun, prevents, in a measure, the coughing and strangling that is liable to occur from the sudden application of the concentrated vapor.

The bag ordinarily lies upon the upper part of the chest, but in operations about the neck and upper part of the body, it may be placed to one side or the other, or upward over the face, by turning the sponge-holder on the rubber hood, the latter retaining its position.

The Advantages of the Inhaler.—The advantages which the writer believes this apparatus possesses are:—

1st. The mechanical act of respiration is entirely free—"the lower end of the bag rises and falls with the respiration, without offering any practical obstruction to the mechanical process" (Squibb), and the breathing can be closely watched.

2d. No part of the instrument is liable to become soiled by expectorated or vomited matters, except the rubber hood, and this is easily cleaned—an advantage of no small importance for the antiseptic days. But it is better to throw the whole apparatus into a basin of water after each inhalation, to free the products of respiration. *No inhaler* should be used a second time without being thoroughly cleansed.

3d. The apparatus economizes ether, the first charge (two ounces) being usually sufficient for a long operation; it prevents, in a great measure, the vapor from permeating the apartment, and affecting the comfort of the operator and his assistants, and especially the anæsthetizer, who often suffers from inhaling a large quantity of the vapor himself.

4th. It is simple in its construction, having no valves, and is inexpensive and portable.

The apparatus, together with a bottle or tin can containing four or six ounces of ether, may be carried in a tin case 9 inches long and $3\frac{1}{2}$ inches in diameter, divided by a diaphragm in the middle—one side of the case for the ether bottle and rubber hood, and the other for the tin tube (the sponge being placed inside of it) and the bag.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint from the *Alienist and Neurologist*, Dr. C. H. Hughes, of St. Louis, gives an interesting note on the essential psychic signs of general functional neuratrophia.

——Dr. Thad. M. Stevens, of Indianapolis, has cogently shown, in a recent reprint, the need of hospitals in Indiana, constructed and controlled by State authority.

——The class work of the pupils of the Illinois Asylum for feeble minded children is given in a brief pamphlet, and presents a gratifying exhibit of improved intelligence.

——Catarrhal affections are so common that Dr. William Pepper's address upon them (reprint from the Trans. of the Am. Med. Assoc.) cannot but be welcome to very many readers.

——An interesting sketch of recent advances in the Specialty of Ophthalmology is presented in a recent reprint by Dr. Julian J. Chisholm, of Baltimore. He considers one of the most important questions of the day in this branch is, How to prevent children from becoming nearsighted.

——In a pamphlet of 134 pages, entitled "Contributions to Practical Gynecology," Dr. S. James Donaldson discusses the treatment of uterine deflexions and dysmenorrhœa. He differs widely from Dr. Sims and his school, in the theory and therapeutics of dysmenorrhœa, and contends that much harm has been done by their teaching. A number of valuable suggestions will be found in the work. (For sale by J. H. Vail & Co., 21 Astor Place, N. Y.)

——The statistics of insanity have a valuable addition in the Fourteenth Report of the Inebriates' Home, Fort Hamilton, N. Y., by Dr. Lewis D. Mason. It presents a careful analysis of 600 cases of alcoholic inebriety. One warning it conveys deserves to be prominently emphasized: "The principal hereditary cause of inebriety is an inebriate father or mother; these records show an inebriate father in 209 of the above 600 cases." The address of the President, Dr. Theodore L. Mason, is in support of the opinion that inebriety is a disease.

——Another severe criticism of the surgical treatment of the late President Garfield comes from the pen of Dr. R. H. Day, of Baton Rouge,

La. (reprint from New Orleans *Medical and Surgical Journal*). The result of his study of the case—and it is a candid and intelligent study—may be given in his own words:—

"I cannot avoid the conclusion that, if the right line of surgical procedure had been adopted at the start, such as I have indicated, and such as is taught and practiced by the most eminent surgeons in every country, those very serious complications which took place during the progress of the case, such as large pus-sacs and long pus channels, might not have occurred; and hence no septicæmia to poison the blood, break down the vital forces, and arrest those efforts at reparation which nature had most evidently commenced. Then, as a logical and pathological fact, the death of the President was not an *inevitable* but an *incidental* result of his wound."

—In order to determine the propriety of bronchotomy in cases of foreign bodies in the air passages, Dr. J. R. Weist, of Richmond, Ind., has made an analysis of 1000 cases (reprint from the *American Practitioner*). His conclusions are as follows:—

1. When a foreign body is lodged either in the larynx, trachea or bronchia, the use of emetics, errhines or similar means should not be employed, as they increase the sufferings of the patient and do not increase his chances of recovery.
2. Inversion of the body and succussion are dangerous, and should not be practiced unless the windpipe has been previously opened.
3. The presence simply of a foreign body in the larynx, trachea or bronchia does not make bronchotomy necessary.
4. While a foreign body causes no dangerous symptoms bronchotomy should not be performed.
5. While a foreign body remains fixed in the trachea or bronchia, as a general rule, bronchotomy should not be practiced.
6. When symptoms of suffocation are present, or occur at frequent intervals, bronchotomy should be resorted to without delay.
7. When the foreign body is lodged in the larynx, there being no paroxysms of strangulation, but an increasing difficulty of respiration from œdema or inflammation, bronchotomy is demanded.
8. When the foreign body is movable in the trachea, and excites frequent attacks of strangulation, bronchotomy should be performed.

BOOK NOTICES.

Two Hard Cases; Sketches from a Physician's Portfolio. By W. W. Godding, M.D. Boston: Houghton Mifflin & Co. 1882. 1 vol., cloth. 12 mo. pp. 257. Price $1.00.

The two hard cases are a young man who committed suicide in the Taunton, Mass., asylum, and Guiteau. As 224 out of the 257 pages are devoted to the latter, the insertion of the other "hard case" is apparently only thrown in to make weight. Nor has it much similarity with that of Guiteau. The writer believes the famous assassin was a lunatic, and criticises at great length the testimony of the experts for the government.

A Rational Materialistic Definition of Insanity and Imbecility, with the Medical Jurisprudence of Legal Criminality founded upon Physiological, Psychological and Clinical Observations. By Henry Howard, M.R.C.S. Montreal: Dawson Bros. 1882. pp. 145.

Dr. Howard argues, from first to last, that animal mind is a product of organic matter; that, therefore, insanity is a physical disease; that there is no such thing as "functional insanity." Much of his argument is illustrated from some well known recent cases, in which he was called as expert witness. He enters to some extent into the best plans of managing convicts, and his suggestions certainly merit attentive consideration. He is also justly severe in his criticism of the common method of employing untrained and often ignorant men to decide on grave criminal charges. In fact, there are a great many thoughts in the volume that cannot but impress the reader.

The Change of Life in Health and Disease. By Edward John Tilt, M.D. Philadelphia: P. Blakiston, Son & Co. 1882. 8vo. pp. 184.

The day of cheap medical books seems to have dawned upon us. This is one of Messrs. Blakiston, Son & Co.'s "New Octavo Series of Standard Medical Books," sold in paper at 75 cts., cloth $1.25 each. Each book is sold separately, so that the purchaser of one good book, that he wants, is not obliged to carry a cartload of dead wood in the shape of uninteresting or third-rate volumes of the series, as is the case with some other series of "Standard Medical Works."

Of course, most books in all such series, where the main point is cheapness, are old, and reprints from English publications, more or less trimmed down. It is safe to say, however, that the reader will surely get his 75 cents' worth if he reads any one of the volumes with care and judgment.

Dr. Tilt, for instance, the author of the volume before us, is a peculiarly pleasant writer and a sagacious gynecologist. His subject is a comparatively unhackneyed one, and his suggestions are sensible and shrewd. What he writes both pleases and instructs.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

HEALTH OF THE TROPICS.

What we lately said about the effects of high summer temperature on the health may further be illustrated geographically by the tropics. It is a prevailing opinion that these are generally unhealthy. Such is not the case, or, when it is so, the causes of the excessive mortality are patent and preventable.

It is not fair to take, for example, the mortality of Madras, which in some weeks runs up to one hundred per thousand per year, and point to it as a result of temperature. In fact, it is the result of starvation, neglect and recklessness.

The highest average temperature in the world is found near the southern extremity of the Red Sea. Yet the medical officers of the English Abyssinian expedition report that the natives of that region are vigorous and long-lived. The virility of the old men was particularly noticeable. It was not at all uncommon for them, when over seventy, to have numerous children. As their wives were strictly secluded, the paternity was indisputable.

Much has been said lately about the unhealthiness of Panama, and the mortality attending the great work of M. DE LESSEPS there in progress. But these accounts have been vastly exaggerated. We are acquainted with gentlemen who have spent years in Panama, and they consider the climate quite salubrious to those who become acclimated.

Within the last week we have spoken with a distinguished scientist who has just returned from a scientific mission to Darien and Panama, and he pronounces the reports about the excessive sickness among the canal employees to be false. Most of the workmen are from the neighboring parts of the tropics, and bear the climate well.

As to the asserted inability of natives of the tropics to bear severe labor, it is completely refuted by the history of civilization. The greatest works of man on both continents have been in tropical or sub-tropical climes. Civilization had its birth in Mesopotamia and Egypt, where the climate is extremely hot, and again in Yucatan and Peru, the one directly under the equator, the other enjoying a warmth which varies from 70° to 110° in the shade.

It is true that a race long accustomed to the bracing air of a northern winter loses somewhat when it is translated to a land of perpetual summer. Much of this, however, is owing to carrying the habits of the cool into the warm latitudes. When such emigrants adopt the clothing, food, and habits of the land to which they go, they suffer much less.

Two potent reasons why modern races have less energy under great heats, are unquestionably, alcohol and tobacco. Both of these profoundly impair the nerve force, and tend to diminish the resistance of the body to extremes of temperature. One able observer attributes the deterioration of the European natives of the tropics principally to the use of tobacco, and his suggestion has much to support it. It is only since these two agents, and especially tobacco, have been widely used, that the vigor of tropical nations has markedly diminished.

TRUE DISINFECTANTS.

Many a so-called disinfectant is employed to-day in a certain solution, when it does not possess any value whatever, under the circumstances. If it is really our intention to disinfect wounds, we must be certain, at least, that we will achieve our object with the remedy we use; if such is not the case, we only irritate without doing good.

The Imperial Board of Health in Berlin has published a number of experiments which have been made by Dr. R. KOCH, with the view of establishing the real value of many so-called disinfectants. It would lead us too far to give the whole procedure employed to ascertain the facts mentioned, and we will, therefore, confine ourselves to giving the more important results of the investigations of this celebrated physician.

Most surgeons have been satisfied to wash their hands and to clean their instruments with a two per cent. solution of carbolic acid. Such a solution is almost inert, and a five per cent. solution is necessary to achieve the desired object.

But what is the most interesting is the fact that *carbolic acid dissolved in oil or water proved itself totally inert!* What do our surgeons who still make use of so-called carbolized oil say to that? KOCH found that carbolic acid, when dissolved in oil or in alcohol, had not the slightest influence on the vitality of any of the micrococci or bacilli.

Concerning sulphurous acid, it was found to be powerless against spores; bacilli and micrococci, when exposed to the fumes in a box, were killed within twenty minutes, but were very little influenced, or not all, when exposed to the fumes in a room at the usual temperature.

Chloride of zinc showed itself just as harmless. A five per cent. solution exerted absolutely no influence on the spores of anthrax, notwithstanding the same had been exposed to the action of the remedy for a period of thirty days.

Of other drugs, the spores of the bacilli were killed by chlorine water, fresh prepared; two per cent. bromine water, one per cent. aqueous solution of corrosive sublimate, five per cent. solution of permanganate of potassium, one per cent. osmic acid, within one day; formic acid, four days; ol. terebinth, five days; solution of chloride of iron, four days; one per cent. arsenious acid, one per cent. quinine (water with muriatic acid), two per cent. muriatic acid, within ten days; ether within thirty days.

Inert or possessing very little influence: distilled water, alcohol, glycerin, oil, sulphur-carbon, chloroform, benzol, petroleum-ether, ammonia, concentrated solution of common salt, bromide and iodide of potassium, 1 per cent. sulphuric acid, sulphate of zinc and copper, alum, 1 per cent. permang. of potash, chromic acid, the chromates and bichromates, chlorate of potash 5 per cent.; boracic acid 5 per cent.; acetic acid 5 per cent.; tannic acid 5 per cent.; benzoate of sodium 5 per cent.; quinine (2 per cent. in water 40, alcohol 60), iodine (1 per cent. in alcohol), thymol (5 per cent. in alcohol), salicylic acid (5 per cent. in alcohol, 2 per cent. in oil).

As regards remedies which prevent the further development of spores, the following results were obtained. The first number means retarding the development, the rest totally preventing it:

Corrosive sublimate,	1 : 1,600.000	1 : 320,000
Oil of sinapis,	1 : 330,000	1 : 33,000
Arsenite of potash,	1 : 100,000	1 : 10,000
Thymol,	1 : 80,000	
Ol. terebinth,	1 : 75,000	
Hydrocyanic acid,	1 : 40,000	1 : 8,000
Oil of peppermint,	1 : 33,000	
Chromic acid,	1 : 10,000	1 : 5,000
Picric acid,	1 : 10,000	1 : 5,000
Iodine,	1 : 5,000	
Salicylic acid,	1 : 3,300	1 : 1,500
Permang. of pot.,	1 : 3,000	
Muriatic acid,	1 : 2,500	1 : 1,700
Camphor,	1 . 2,500	
Eucalyptol,	1 : 2,500	
Benzoic acid,	1 : 2,000	
Borax,	1 : 2,000	1 : 700
Carbolic acid,	1 : 1,250	1 : 300

But as, for purposes of disinfection, the micro-organisms must be killed, and in the shortest possible period, and the effect of retarding the development of the spores (antiseptic) is not sufficient, only the following remedies can, according to KOCH'S experiments, be said to be of value: corrosive sublimate, chlorine, bromine, iodine. Bromine in form of vapor is, as concerns rapidity of action, superior to chlorine and iodine.

Notes and Comments.

Sulphuretted Hydrogen as a Remedy for Tuberculosis.

Dr. Froschauer has published a number of successful experiments which he made with sulphuretted hydrogen on animals, as a remedy against septicæmia. In connection with this, Prof. Arnaldo Cantani (Neapol.) has written to the *Centralb. f. Med. Wissensch.*, No. 16, 1882, and mentioned that among other experiments he made with disinfectants, to find out their value as curative remedies in tuberculosis, he has instituted also a number of observations with sulphuretted hydrogen. This is given to the patients internally, in the form of water impregnated with the gas. Besides, the patients are kept for a long time in a room the air of which is loaded with the gas, which the patients inhale. The first few days the latter object somewhat to this method, the odor evidently not being very agreeable to them, but in a short time they become accustomed to it, and as they feel the decided benefit they gain by this procedure, willingly continue it.

These observations are not concluded as yet, but Cantani is satisfied that, so far, the following results have been achieved :—

The fever disappears within a few days, and does not return as long as the inhalations are continued. The same is the case with the chilly sensation and the night-sweats, which usually cease. The local morbid process does not make any further progress, and is undoubtedly arrested for the time being. The expectoration diminishes decidedly in quantity.

Cantani intends to continue these experiments, and will not fail to report any further results.

Skin Eruptions in Locomotor Ataxia.

Charcot, Velpian and others have observed the presence of skin eruptions (papulæ, maculæ, etc)., in cases of sclerosis of the posterior columns. These eruptions have been found to be in intimate connection with the lancinating pains of tabes. J. Strauss ("Des ecchymoses tabé tiques, à la suite des crises de douleurs fulgurantes;" *Arch. de Neurologie, etc.*, 1881, No. IV), has now noted ecchymoses in the skin appearing in tabes after the paroxysmal pains. From a description in the *Centralbl. f. d. Medic. Wissensch.*, 1882, No. 16, we take the following :—

These ecchymoses show themselves only after the attacks are over, and they resemble the spots which result when the skin is pinched severely; they have an irregular, round shape, and their size varies from that of a split pea to that of a silver half dollar. There are, usually, several (3–4) spots in one extremity. They are painless, and are observed only after a very severe attack of pain, and according to the nature of the latter the spots are one- or double-sided. The spots are mostly to be found above the seat of the pain, and differ from Charcot's skin eruptions by not following the course of the nerve. Exceptionally, they appear on the extremity which is not the seat of the pain. Strauss considers these spots as rather frequent in locomotor ataxia, and brings them in direct connection with the morbid alteration of the posterior columns of the spinal cord. He thinks that they are reflex phenomena (irritation of the vasodilators). This seems possible, if we remember the hemorrhages which have often been observed in cases of tabes after gastric and rectal crises (paroxysms of intense pains beginning either in the stomach or in the rectum).

Artificial Alimentation in Nervous Vomiting.

M. Gilbert Ballet, in a recent number of *Le Progrès Medical* (June 17th), gives the full observation of two cases occurring in M. Charcot's service at the Salpètrière. Both patients were hysterical, one very much so ; there was almost complete intolerance of the stomach, every species of food and drink being vomited. Both patients, on entering the service, were placed on an exclusive milk diet, but without beneficial result, as the milk was constantly and very rapidly ejected from the stomach. Then a simple tube of soft rubber (tube de Faucher) was passed into the stomach, and one quart of milk injected ; it was retained but a short time. The next day but a pint at one time was injected, and retained, and from that time milk was thus constantly introduced into the stomach and retained. This species of alimentation was continued for about fifteen days, about two or three quarts of milk being introduced daily, with four eggs beaten up and a spoonful of beef essence. After these fifteen days the first patient had gained eight pounds in weight and was able to eat without the tube. The results were equally good in the other case.

This method of artificial or forced alimentation, which is at present attracting considerable attention in the French capital, was first principally experimented by M. Debove, in phthisical patients who had fallen almost into a state of marasmus and were unable to retain any species

of food on the stomach. In such cases it gave unhoped-for results, and though it is not so constantly beneficial in incoercible nervous vomiting, it has in many cases given excellent results.

Anosmia.

In the *Lancet*, Dr. E. H. Jacob says that the total loss of smell is so uncommon, and its recovery so very rare, that the notes of the following case possess interest. A woman, aged forty-five years, fell from a stool, striking the back of her head. Ever since (some years) she has been absolutely without the sense of smell. She did not complain of pain, but was nervous, weak and excitable. Iodide of potassium, fifteen grains three times daily, was ordered. In a week she said that her head was clearer, but the sense of smell was not improved. Subsequently a constant current, gradually increased to the highest bearable extent (about twenty cells), was passed from the mastoid process to the nasal bones, for five minutes on either side. This process was subsequently repeated four or five times, and while the sense of smell was not entirely restored, it was very much improved.

Sulphurous Acid in Typhoid Fever.

Dr. J. Burney Yeo says, in the *Practitioner*, that, his attention having been directed, by some medical friends, to the value of sulphurous acid in typhoid fever, he decided to give it a trial. The first two cases in which he used it progressed favorably to recovery, but they were of a very mild type. Finally a severe case presented itself. On the morning of the fourth day of the fever the sulphurous acid was commenced, in half drachm doses every four hours, and continued uninterruptedly for twenty days. The temperature ranged between between 102° and 104°, the evening temperature on the ninth day being 103.6°. On the tenth day there was a notable fall of temperature. It did not rise above 102° during the tenth, eleventh and twelfth days. On the thirteenth day there was another fall, the evening temperature being 101.2°, and for the next six days the evening temperature only reached on one occasion 101°. From the ninth to the nineteenth he seemed to be doing well. On the latter day he complained of abdominal tenderness. On the twentieth day the temperature began to rise again, and continued to rise gradually till the evening of the twenty-second day, when it was 103.8°. It kept at this point, but with wider oscillations than before, until the twenty-eighth day, when it reached 104.2°, the highest recorded. He died suddenly on the evening of the twenty-ninth day, with symptoms of perforation. The author concludes from this case that sulphurous acid seems to be a remedy of some value as an antipyretic in cases of typhoid, and considers it worthy of note that in this case, notwithstanding the extent and gravity of the intestinal ulcerations discovered post-mortem, the temperature was never very high, only twice reaching 104°. This remedy must be given further trial before we decide on its merits.

Hypodermic Application of Purgatives.

After L. Lewin and Kohn had published a number of observations concerning the action of certain purgatives, if employed by the hypodermic method, A. Hiller, in Berlin, made some experiments, which he reported last month in the *Zeitschr. f. Kl. Med.*, iv, 40.

The remedy mostly recommended for this purpose is *aloin*. Hiller observed, after injecting 0.15 to 0.2 grams of the remedy, a copious and soft discharge within four to six hours. But the action depends much upon the preparation of the remedy.

Colocinthinum purum (prepared by Merck, in Darmstadt, a grayish yellow powder) produced, in the dose of five to ten mgrm., watery stools with slight bellyache. A solution is made with water, glycerine and alcohol, but the injection is very painful. Just as painful are the injections made by a similar solution of *citrullin*, dose 0.005–0.01.

The same can be said of *acidum cathartinicum* (made from senna), dose 0.2 to 0.3.

We may conclude, therefore, that these injections produce too much pain, while aloin, which does not cause this inconvenience, is very unreliable.

Ammoniated Mercurial Peptones.

M. Martineau recently read a new memoir before the Soc. Médic. des Hôpitaux, on the treatment of syphilis by the hypodermic injection of these prepared peptones. It may be said that this method of treatment is at present used in many hospitals, but has not yet received sufficient attention in private practice. M. Martineau has treated 600 patients in this way, and made 11,000 injections. He regards the method as almost perfect, without contra-indications or accidents of any description. He has observed neither phlegmon, abscess, or eschar, even among diabetic patients. Salivation and mercurial

stomatitis or gastric and intestinal troubles are infrequent.

This method has a more efficacious action, and is more rapid and energetic than other forms of treatment. Under its influence the bodily weight increases and the number of globules multiply. Finally, considering the rapid beneficial effects of the treatment, its value at a financial point of view should recommend its introduction into civil and military hospitals.

According to M. Martineau, it invariably diminishes the sojourn of the patient in the hospital, and as from 3000 to 4000 soldiers are constantly under treatment for these disorders in the military hospitals, the saving in time and money would be very great.

Dried Blood.

In the *Société de Biologie* (June 3, 1882), Regnard reported the result of his experiments, by which he intends to demonstrate the value of boiled and dried blood as an aliment. He had selected sheep for this purpose. Of six sheep he gave to three this powdered blood in addition to a certain quantity of their usual vegetable food, and to the other three the latter alone. The last three died; the first developed themselves splendidly. Should this good success continue the result will be of importance, as the immense quantity of blood, which in slaughtering establishments is now only a product of waste, will become useful, and a valuable article of commerce, providing a cheaper food for certain animals. Regnard obtained also favorable results in a rachitic child, eighteen months old.

It would be well for our Commissioner of Agriculture to aid experiments of such kinds. They would be of far more benefit for all than many of the fancy experiments, for which too often large amounts of money are thrown away.

A Common Mistake Concerning Chloride of Potassium.

It is well known that chlorate of potassium is a very good remedy to gargle the throat, but comparatively few physicians are aware of the fact that it is not this remedy which is so successful in mercurial stomatitis, but chloride of potassium.

Prof. Wertheim draws the attention of physicians especially to this fact (*Wiener Med. Blätter*, 15, 1882). He reminds them that the formula of the first is, $KClO_3$, but that of the second KCl. He says that the chlorate should never be used, as in concentrated solution it may even prove very harmful; while the chloride is very innocent; a specific in sore throat, and especially in mercurial sore mouth, and very analogous to common salt, which is simply a chloride of sodium, instead of potassium. In America the chlorate is commonly used; no wonder, therefore, that it is not found here as efficient as in France and Germany, where they use the chloride.

Sugar in Pleuritic Effusions.

H. Eichhorst (*Zeitschr., f. Klin. Med.*, iii, p. 537) observed, in the serous effusion of a case of pleurisy, notwithstanding the absence of sugar, that the latter formed very soon. He examined, therefore, seventeen cases of serous exudation, with particular care; in all these cases the fluid was withdrawn with the aid of a Pravaz' syringe, and immediately analyzed. Of these seventeen cases the effusion contained, in ten cases, sugar; two were free of sugar and of ferment. The presence of sugar seemed to exclude the presence of the sugar-forming substance, which was found, however, in the others. The ferment, which was detected in two cases, had the peculiarity not to be destroyed by boiling. To examine for the sugar-forming substance, the exudation was boiled, with the addition of sulphate of sodium. When cold the addition of a solution of iodine and iodide of potassium produced a blue-violet color.

Isolation in the Paris Maternite.

M. Tarnier, in a letter recently addressed to the Soc. Médic. des Hôpitaux, recalls the very extraordinary results obtained by isolation, the use of antiseptics, and all means proper to ward off contagion. In the new pavilion he has had constructed, in which each chamber can only be entered by a separate door opening outwardly, without any aperture toward the hospital except a single large pane of glass let into the wall, permitting the surveillance of the patients, he has had but six deaths in 1200 cases of labor. Within the past few years even there have been 600 cases without a single death. No statistics ever published have shown such favorable results as these of M. Tarnier.

Opening of the Chest in Hydatid Cyst of the Lung.

At a recent meeting of the Soc. Médicale des Hôpitaux (June 23) M. Bucquoy presented a remarkable case of hydatid cyst of the lung, treated and cured by incision of the chest wall.

A man of 39 years of age presented himself, with the signs of dry pleuritis on the right side;

later the general condition became bad, and all the signs of pneumothorax were found.

By aspiration, more than two quarts of pus were withdrawn from the chest, but no improvement followed; hectic fever appeared, with fetid breath, discharge of pus from the mouth, and a second aspiration gave but about three ounces of very fetid pus.

An incision in the chest wall was then made, and the hydatid cyst extracted; rapid recovery ensued, a fistulous passage into the chest remaining.

Nasal Polypi and Asthmatic Attacks.

M. Joal, in an interesting memoir published in the *Archives Générales*, calls attention to an unrecognized cause of asthmatic attacks. Trousseau and Gueneau de Mussy had already insisted on the causative relations existing between certain forms of coryza and asthma. The author of this memoir mentions eleven cases observed by himself, where the asthmatic attacks disappeared soon after the removal of nasal polypi; in several cases the attacks reappeared when the polypi had again regained their former size. The author remarked that these patients were in general subject to arthritic manifestations, and that it was only in certain exceptional cases that the nasal polypi provoked respiratory derangement. The author is of opinion that the polypi in such cases cause irritation of the nasal mucous membrane, inducing thus, by reflex action, a spasm of the muscles controlling respiration.

Micrococci of Lupus.

Dr. M. Schüller has been able to detect in the smaller papulæ of lupus micrococci. They are observed in the larger papules too, but it is difficult to find them there. They were never absent in the sebaceous glands in the region attacked by the disease. This fact would seem to explain the good results which have been gained by the local application of pure carbolic acid.

Neuralgia of the Trigeminus Cured by Amputation of the Vaginal Portion.

In the *Centralbl. f. d. Medic. Wissensch.*, 1882, No. 16, we find the following interesting case reported: Dr. J. Holst (*Petersb. Med. Wochschrift*, 1882, 1) had a patient who, after having taken a cold bath during her menstruation, was attacked by dysmenorrhœa, which was cured by a course of bathing at Kissingen. But soon a very severe right-sided neuralgia of the trigeminus (2d and 3d branch) made its appearance, which exacerbated decidedly during each menstrual period. Life became a burden to her. Holst found the vaginal portion swollen and indurated; there was endometritis colli follicularis. He amputated the neck and the neuralgia disappeared; the first menstruation after the operation was still a little painful, but the next was free from pain. All dysmenorrhœa and neuralgia have since ceased, and the patient enjoys splendid health.

Resection of the Stomach.

The *Allg. Med. Central Zeit.* reports, under April 19th, from Bamberg, that the physician-in-chief of the surgical division of the city hospital, Dr. Nebinger, performed resection of the stomach on a patient over forty years of age. The cause was cancer. The patient, who on April 4th, was able to take solid nourishment again, is doing very well, and there is every hope that he will fully recover from this dangerous operation. It is doubtful, however, if the malignant growth will not return.

Paralysis After Extraction of a Tooth.

F. H. Balkwill, D.D., of Plymouth, extracted, a short time ago, a lower molar tooth for a young man. After the extraction the patient complained of numbness of the skin over the chin. Later, this sensation changed to one of pricking needles. The anæsthesia reached from the median line of the lower lip and the chin to a little over the region of the foramen mentale. About a month later normal sensation returned.

The extracted tooth exhibited, on the lingual side of the posterior root, near the point, a transverse fossa, which had undoubtedly been made for the passage of nervus inframaxillaris. During the extraction the nerve received, evidently, a severe concussion, or was partially torn; hence the anæsthesia.

A New Mydriatic.

Hyoscin, prepared by Ladenburg (E. Emmert, *Corresp. Bl. f. Schweig. Aerzt.*, 1882, 2) and crystallizable by hydroiodic acid, has proved to possess, if dropped into the eye, a remarkably rapid mydriatic effect, and surpasses, in this respect, atropia, in a high degree. But the solution should be only a half per cent. one, as stronger solutions (1½ per cent.) cause already general symptoms as: unconsciousness, disturbances of articulation, vertigo and dryness of the throat. It may be mentioned, that this preparation seems to be well tolerated by the conjunctiva, even if kept a long time in contact with it.

Special Reports.

No. X.—THERAPEUTIC PROGRESS.

JABORANDI IN TYPHOID FEVER.

In the course of an article on this subject in the *Medical Press and Circular*, Dr. Richard Ryder says that, having had his attention called to the value of sudorific treatment in the early stages of typhoid fever, he has used jaborandi extensively, and believes it to be the most valuable we possess, in the early stages, not only of febrile, but in acute and inflammatory affections, whether arising from cold, blood poisoning or other causes. He believes jaborandi to possess the power of eliminating from the human system, through the skin, almost any specific poison, if resorted to at once and before the poison has had time to set up its specific action. He says:

"My attention was first called to this plan of treatment many years ago, by hearing of a gentleman who held the position of resident physician to a large fever hospital. His belief was that he had frequently contracted both typhus and typhoid fever in the discharge of his duties, and his novel mode of arresting it was to mount his horse and ride for ten or fifteen miles, regaling himself on the road with sundry glasses of whisky punch. He would then return in a bath of perspiration, and feel no more of his dreaded enemy.

"A short time after hearing this account, I saw a lady who had been suddenly taken ill with all the premonitory symptoms of typhoid, and as she had suffered but a short time before from that disease, she was convinced in her own mind of the nature of the attack, and on being questioned said: 'I feel exactly as I did when I was sickening for typhoid fever.'

"I immediately resorted to active sudorific treatment, assisted by numerous blankets, covering all with a mackintosh sheet, to prevent the least evaporation. I then kept up the action of the skin till all the abnormal symptoms had subsided. In less than ten hours from the time of commencing the treatment the patient was convalescent, only complaining of weakness. That is more than twelve years ago, and since then I believe I have been the means of arresting a very large number of similar cases.

"The great difficulty I found in most cases was to produce a free action of the skin; if I could only produce that I had little fear for the result. The introduction, therefore, of jaborandi as a therapeutic agent was hailed by me as one of the most valuable additions to our materia medica. I look on it, in the early stages of fever, in the same light as salicylate of soda in acute rheumatism. I have found it reduce the temperature to its normal standard within a few hours, removing at the same time all abnormal symptoms.

"The preparation of jaborandi which I find the most convenient and reliable is the fluid extract. The dose being small, it is not likely to produce nausea or sickness. Some patients are more impervious to its effects than others. So I begin with the minim dose, gradually increasing it every hour till the full action is obtained. The effects are more readily induced by putting the patient into bed between the blankets.

"The sweating usually commences in from three to five minutes, if the dose is sufficiently large and the preparation a reliable one. If there is no action of the skin from the first dose, within the hour I repeat it, giving double the quantity for the next. In conclusion, I must say that I have the most implicit confidence in this plan of treatment, and believe that jaborandi will effectually stop an attack of fever if taken in its first stage. But it frequently occurs that the medical man does not see the case till it is too far advanced to derive any benefit from it."

ANTISEPTIC INHALATIONS IN THE TREATMENT OF LUNG CAVITIES.

In the *Lancet*, Dr. Lawrence Humphrey reports two cases in which cavities in the lungs were treated by antiseptic inhalations, with marked benefit. Dr. Sinclair Coghill's respirator inhaler was used. The following solution was inhaled: two drachms each of the ethereal tincture of iodine and carbolic acid, one drachm of creasote and one ounce of rectified spirits. Ten drops of this solution was used in the respirator, morning and evening. The patient soon learned to inhale by the mouth and exhale by the nose, and was able thus to employ the respirator for one hour, in the morning and evening. In these cases the tuberculizing process had not commenced, the cavities being considered due to the breaking down of pneumonic deposits.

Dr. Thorowgood, under whose care these cases occurred, says:—

"My experience of all kinds of warm steaming inhalations in chronic phthisis has been most unsatisfactory; but in the introduction of this respirator inhaler we seem to have gained some real advance toward a means of checking purulent formation in lung cavities. The creasote, I expect, is the most valuable agent as an inhalant, and it is always necessary to train the patient in the use of the respirator, by teaching him to inspire through the mouth and expire through the nostrils."

KORONIKO IN CHRONIC DYSENTERY.

The *Medical Times and Gazette* says that Dr. J. Jardine, writing from Kiukiang, in the *Chinese Imperial Maritime Customs Medical Reports*, says that dysentery, acute and chronic, was very prevalent in that community during the autumn of 1880. Acute dysentery had generally become subacute or chronic before the patients applied at the hospitals, so that the chronic form had generally to be dealt with:—

"As every one knows, these are the difficult cases to influence speedily by drugs, and with the Chinese a change of air or sea voyage is beside the question. In these cases I was induced

to try koroniko, from the *Veronica parviflora*, which is largely used in New Zealand as a remedy in dysentery and diarrhœa, and some of the results exceeded my most sanguine expectations. Many who received the drug did not return to report themselves; but I have notes of three cases of chronic dysentery, varying in duration from six weeks to four years, and voiding from twenty to thirty motions containing blood and mucus daily. Fifteen doses of tincture of koroniko reduced them to one-half, other fifteen doses reduced them to three or four daily, and a third like quantity effected a complete cure. Judging from the few cases I have been able to follow, I augur a brilliant future for this remedy in the chronic forms of the disease."

PILOCARPIN IN URÆMIC CONVULSIONS.

In the *Medical Press*, July 5th, 1882, Mr. James Lemont reports the case of a laborer, aged 44, who was admitted to the hospital with swelling of the legs and abdomen, and difficulty in breathing, of twelve months' duration. His mother and brothers died of dropsy. He gave no history of scarlet fever or rheumatism, but had been a great drunkard and much exposed to sudden changes of temperature. Urine much diminished in quantity, albumen plentiful, fatty casts. He was ordered acetate of ammonia and compound jalap powder, with a vapor bath every evening. On the second night after admission he had become unconscious and had several convulsions. Chloral hydrate and potass. bromid. (forty grains of each), were given by enema, and a wet pack was used to induce diaphoresis, but without the slightest effect. One-third of a grain of pilocarpin was then injected subcutaneously, and in less than five minutes there was profuse perspiration, which lasted several hours. The patient remained unconscious for twenty hours, but there was no return of convulsions. At the end of a month there was no trace of œdema. The pilocarpin was given once more.

Dr. W. Brown Moir describes, in the *Lancet*, a case of uræmic convulsions and coma in a boy aged twelve, who was suffering from acute nephritis. An injection of a third of a grain of nitrate of pilocarpine and an enema of chloral hydrate were given. Copious perspiration was produced, but the convulsions continued, though less severe. On the following day the same treatment was repeated, with diaphoresis and decided abatement of the convulsions.

As soon as the ability to swallow returned, benzoic acid in two grain doses was administered every hour, and the strength supported by small enemata of beef tea, to some of which was added a little brandy. From the time the power of swallowing returned benzoic acid was the only remedy used, and its use was continued for six days. It was given as above for the first forty-eight hours of that period, and after that in five-grain doses, every three hours. During these six days the patient, though free from convulsions and able to swallow, lay in a semi-conscious state, requiring to be spoken to loudly and shaken, to get him to take anything. His vision was completely lost. He knew no one, could see nothing held up before him, not even a bright light, pupils still continuing slightly dilated. Under the steady use of the acid the urine increased in quantity, grew lighter in color, and the albumen lessened daily. His mind became clear, and vision once more distinct, convalescence being gradually established. Whether the theory regarding carbonate of ammonia circulating in the blood being the cause of uræmia be correct or not (and the recent experiments of Oppler and Zalesky seem to indicate that it is not), this is the second time within my own limited experience of such cases in which benzoic acid has done good service. Whether its mode of action be the conversion of the poisonous alkali into a harmless acid and salt, or in what other specific way it acts, I am not prepared to say, but the above is strictly in accordance with facts.

TREATMENT OF DIPHTHERIA.

The *Medical Press* says that Dr. Deuker, who, during twenty-four years of very extensive practice in the Children's Hospital, St. Petersburg, has treated upward of two thousand cases of diphtheria, and tried all the remedies, both internal and external, employed in this affection, has obtained the best results from the following method, which he has employed for the last ten years. As soon as the white spots appear on the tonsils he gives a laxative mainly composed of senna, which produces an abundant evacuation. When the purgative effect has ceased he gives cold drinks, acidulated with hydrochloric acid, and every two hours a gargle composed of lime water and hot milk in equal parts. Dr. Deuker affirms that when this treatment is commenced early it is generally and rapidly successful.

THERAPEUTICS OF INFANTILE HEREDITARY SYPHILIS.

Although not strictly appropriate to this report, yet this subject possesses so much interest and is so frequently brought to the notice of the physician, that the following lecture on this subject, delivered by Dr. Archambault at the Hôpital des Enfants Malades, and translated from the *Gaz. des Hôp.* by the *Med. Times and Gazette*, will prove of immense service:—

"No question is perhaps more important than that of the treatment of syphilis, especially in an

infant who has acquired it by inheritance. If it is rare in the adult for this to prove a question of life and death, it unfortunately is not so with the new-born child; and accordingly as treatment is well or ill devised, and well or ill carried out, the infant will be cured or will perish. This importance of treatment is such that it ought even to precede birth, wherever that is possible; that is to say, when a pregnant women is averred to be the subject of syphilis. The physician is thus, according to an old expression used in the law courts, *curateur au ventre*. Every woman certainly the subject of syphilis ought to be submitted to the anti-syphilitic treatment of the adult. Intervention should also take place in cases where, although no longer presenting any of the manifestations of the disease, the epoch is yet not distant at which some of the symptoms were observable. Suppose the mother exhibits no traces of syphilis, while the father is syphilitic; it is more difficult to decide. Nevertheless, if you suspect that she has had, unawares to herself, some of the manifestations of syphilis, do not hesitate to intervene; while if you feel certain that she has had nothing of the sort, abstain. I may say that, with regard to all the cases that have come under my notice, every time an infant has been born syphilitic its mother has been the subject of syphilis. Quite lately, I had occasion to observe, in a most honorable family, hereditary syphilis in an infant whose father had a chancre, followed by secondary symptoms, ten years before. He had married only a year ago, and had syphilized his wife, and consequently the infant. We are often consulted on the question whether a young man, formerly the subject of syphilis, can marry with impunity. In such cases we should always act with great severity; in proof of which you have the case I have just cited, of syphilis having been communicated at the end of nine years; and I could give you many other examples.

"Should one intervene on the earliest manifestations of hereditary syphilis? The question should answer itself in the affirmative; but yet some authors maintain that we must wait some time, in order that the infant may bear the treatment without danger. That is, I declare to you, most fatal advice, for you will find the child wasting away, while, on the contrary, if there is anything that can strengthen it, it is active intervention. When the child is suckled by its mother or nurse, you have two modes of treatment, the one complementary to the other—the direct treatment of the child, and the indirect treatment of the mother or nurse, to whom you give the suitable medicinal substances. But this latter mode of treatment is only an adjuvant, and employed alone it would prove absolutely insufficient. How is the infant to be treated directly by mercury? The preferable mode is to administer the sublimate dissolved in water or in milk, with which it will form without any inconvenience (notwithstanding what has been said about it) an albuminate of mercury. Baumès commences with one, one and a half, or two milligrams, progressively increasing the dose to six milligrams in the twenty-four hours; Bertin commences with two milligrams, to reach four, his maximum dose; Cullerier begins with five milligrams; and Bassereau prescribes the dose for an adult reduced to a fourth or a third, which comes to pretty much the same. A milligram and a half seems a very small affair; but if you compare the weight of a child with that of an adult (the mean weight of an infant being five kilograms, while that of an adult is seventy), you will find that the dose advised for infants is comparatively a large one. For my part, I ordinarily commence with a milligram and a half per diem, and, according to the condition of the little patient, gradually reach the maximum of five or six milligrams. All depends upon whether we have to do with a slight syphilis or with grave symptoms. In certain cases, when I have found myself in the presence of a true cachexia with gastro-intestinal disturbance, I have begun with four milligrams from the first day. We may employ the *liquor* of Van Swieten, which is a solution of the sublimate in the proportion of a thousandth part, and which allows the quantity of mercury you wish to give to be very easily dosed. Thirty drops of this *liquor* correspond to one milligram and a half of the sublimate, and I prescribe them to be taken in milk, in three doses, morning, afternoon and evening, increasing by two drops every other day, until the maximum is attained. In the infant you do not find, as in the adult, any positive sign of the mercurial saturation of the organism, and the sole rule you have to guide you is the local and general condition of the child. Thus you will no longer continue to increase the dose when you find vegetations subsiding, ulcerations filling up, and spots disappearing, etc.

"Mercurial treatment has been accused of inducing intestinal disturbances and provoking diarrhœa; but it is exactly the contrary of this which takes place, and, save in some exceptional cases, the diarrhœa, which existed prior to any treatment, disappears almost always under the influence of mercury. Still, should the diarrhœa persist, or should it appear under the influence of a peculiar disposition, you may add, according to its intensity, a half or a whole drop, or even two drops, of laudanum to the *liquor;* or still better, you may prescribe five centigrams of *hydrarg. cum creta* twice a day, to which you may add, if required, half a drop of laudanum. External treatment may be employed either alone, or concurrently with internal treatment; but for my part I only have recourse to it when mercury is not tolerated internally, and on the condition that it is very effectually administered. A gram and a half of mercurial ointment may be rubbed in night and morning, continuing it for a considerable time, and varying the part on which the friction is made, in order to avoid producing eczematous eruptions. For the same reason the frictioned parts should be washed, from time to time, with mild soap. The curative effects of these frictions do not admit of doubt, and in cases of slight manifestation of the disease they may suffice. Nevertheless, whenever it is possible, I associate the internal with the external treatment. Sublimate baths also may be employed as adjuvants to general treatment in cutaneous manifestations of the disease. The dose for an infant is from two to six grams per

bath. This may be used even in any metallic bath, on condition of adding ten to fifteen grams of the chlorhydrate of ammonia, or even of simple chloride of sodium, in order to obviate the effects of the decomposition of the mercurial salt in presence of a metal.

"Such is the mode of treating the general accidents of hereditary syphilis in infants, a treatment to which we must add a good hygiene. Thus, alimentation should be severely watched, and especially if the child is brought up on the bottle, which is the case when the mother will not suckle her infant, and under the difficulty there is of finding a nurse who will consent to suckle a syphilitic infant, in the face of the risks she runs, unless she herself has been syphilized. Great care also must be taken to preserve the infant from the impression of cold, which may induce severe intestinal disturbances. It is well known, in fact, that if syphilis is of more frequent occurrence in warm climates, it is also there cured more easily."

COD-LIVER OIL IN YOUNG CHILDREN.

The *Lancet* says:—

If diarrhœa or vomiting be present—speaking generally, though by no means absolutely—the use of cod-liver oil internally is contra indicated in young children, but if neither of these symptoms be present, we cannot recall a more useful agent in the marasmic conditions of infancy. We cannot fix any limit of age, but we have seen infants of a month old distinctly improve while taking it, and we should have thought the enormous benefit of this agent to rickety children, both under and over twelve months old, had become a truism in medicine. Even in hereditary syphilis, although it will not take the place of gray powder, in our experience, cod-liver oil is a most valuable adjunct in treatment. Also, besides generally helping in the nutrition of a feeble infant, observant mothers often point out that the regular employment of cod liver oil assists in overcoming the occasional difficulty of constipation.

ETHER AND THYMOL IN CHRONIC RINGWORM OF THE SCALP.

In the *British Medical Journal*, Dr. Malcolm Morris says:—

That chronic ringworm of the scalp is a difficult disease to cure, every practitioner will admit. There are two propositions, as regards treatment, which I desire to bring under the notice of the profession. But, first, I must briefly refer to the factor in the problem we are called upon to consider—a fungus growing on and in the hairs, extending deeply into the follicles, as far as the roots.

In a paper published in the early part of last year, I pointed out that two things were essential in the treatment of this disease; first, some drug which is capable of destroying the fungus, and so preventing its further development; and, secondly, some vehicle to carry this drug to the part of the follicle where the fungus exists and grows. Arguing, from analogy, that certain chemical substances, called antiseptics, had the power of destroying certain low forms of vegetable life, such as bacilli, micrococci, and bacteria, I suggested that thymol or menthol should be used as the parasiticide, and that chloroform would answer the purpose as the absorbent. But, as the latter was volatile, I added oil to the compound, to prevent evaporation. While trying this liniment, of thymol, chloroform, and oil, in a large number of cases, I was struck with the fact that in some of them, in spite of the constant application of the remedy, the disease appeared on other parts of the body, and also on parts of the head previously free. It seemed difficult to understand that, in a strictly antiseptic medium, spores could be carried from part to part and live; but such seemed to be the case, for in some instances, when the liniment had been used too freely, and had run down the neck, fresh spots of the disease showed themselves in that region. During the time I was considering this difficulty, I found that Koch, in Berlin, had been making experiments on bacillus spores with various antiseptics, and found that these spores lived and developed even after being placed in carbolic oil (one part in twenty) for one hundred and ten days. This, I think, is a very strong argument that neither oil nor fat of any kind should be used when the full action of an antiseptic is required.

Of course, I am fully aware that all the best authorities recommend strong ointments, mercurial or otherwise, though for a very different reason from that I have been describing. They care little or nothing about the antiseptic action, so long as inflammation of the follicle, more or less severe, be produced. The spores are said not to live in inflammatory products (Thin). But surely cases are not uncommon in which the disease is transplanted to healthy parts by means of the discharge. I have seen a case in which croton oil was used to a single patch, and in a short time the head was covered with small centres of infection. In this case, the spores were carried in the discharge.

And, again, have not all the old chronic cases we see in practice, some of them of four or five years' duration, been cases treated by constant attacks of inflammation, and yet with the result that spores have been found with ease? My view is that to produce inflammation of a slight kind is useless; and that a severe kind is unjustifiable, on account of the risk of destroying the follicles altogether, and producing baldness.

To return to the question of fats: if fat of any kind from without protects the spores, as Koch asserts, the natural fat or sebaceous matter must have a similar effect. For this reason, I have tried to remove the fat by means of ether, and have abstained from using ointments or oil in the treatment. I wash, or more strictly dab, the patch each morning with ether, rectified spirits of wine and thymol, in the following proportions: ether, five drachms; rectified spirits of wine, two drachms and a half; and thymol, half a drachm—applying during the day glycerine with a very small trace of perchloride of mercury. Petroleum may be used in the place of the ether and spirit. One drachm and a half of petroleum oil takes up five grains of thymol. The ether or petroleum is of greater value than would at first sight appear, and for the following reason: There is a disease of the scalp known as

seborrhœa sicca, the chief characteristic of which is the falling out of the hair. This is caused by the absence of the natural fat in the sebaceous matter. It is cured by stimulating the glands to action, and by adding fat artificially. In the ringworm patch, we want the diseased hairs to fall out; and, by producing a condition similar to seborrhœa sicca—that is, by making the part very dry—we can actually produce this effect. Instead, therefore, of epilating by means of forceps, which is useless, as the hair breaks at the neck of the follicle, leaving the diseased part behind, we can epilate by dissolving the fat, and thus loosening the hair. In this way we can in a few days remove all the broken and diseased hairs.

THERAPEUTIC PROPERTIES OF QUINIA IODATE AND BROMATE.

At a recent meeting of the Medical Society of the College of Physicians in Ireland (*British Medical Journal*), Dr. Charles A. Cameron read a paper on the therapeutical and physiological properties of these new salts, which he had recently had prepared and introduced to the notice of the medical profession. He pointed out that the researches of Arthur Gamgee, Priestley and Larmuth had shown that the three forms of phosphoric acid and of vanadic acid had very different degrees of physiological activity. The salts of orthophosphoric acid were almost inert when their bases were inactive, while the pyrophosphates and metaphosphates were poisonous. The orthovanadic acid was poisonous, but pyrovanadic acid and metavanadic acid were still more poisonous. The high physiological activity of the pyrophosphates and metaphosphates had been attributed to the unsaturated condition of their nuclei; these salts were not statical, for they could take up additional basic material. Further, when superoxygen compounds were introduced into the system, it might be expected that their oxygen, being loosely combined, would unite readily with elements of the blood Dr. Cameron believed that the chlorates, bromates and iodates were more active physiological agents than the corresponding chlorides, bromides and iodides. Chlorate of sodium was more powerful than chloride of sodium or common salt. It might be inferred from analogy that iodate of potassium was a more active physiological agent than iodide of potassium. Some years ago Dr. Cameron suggested the use of ferric iodate as a substitute for the unstable ferrous iodide, and more than a year ago he had prepared an iodate of quinine in combination with an effervescing mixture. Each drachm of the effervescing iodate of quinine contained two grains, or one dose, of the iodate. It had been found very useful in the treatment of neuralgia, severe articular pains which had resisted the employment of the usual remedies, sluggish forms of pulmonary congestion, secondary syphilitic disease, and malarial enlargement of the spleen. Bromate of quinine might be prepared by precipitating barium iodate by sulphate of quinine, or by neutralizing quinine with bromic acid. It occurred when air-dried in small asbestos-like masses, which under the microscope was seen to consist of very long needles.

Dr. H. Colpoys Tweedy had seen good results from iodate of quinine in pulmonary congestion. Brigade Surgeon Jackson asked what was the relative expense of these new preparations compared with sulphate of quinine, with the action of which in intermittent fever he was much disappointed. Dr. Quinlan considered that the useful feature of the iodate of quinine consisted in the fact that its acid easily separated from it, thus leaving it circulating in the blood in a basic form. Mr. Knott had no doubt that the large proportion of easily dissociated oxygen present in both the iodate and the bromate of quinine would add materially to the physiological activity of these drugs. He should not be surprised to hear of the bromate of quinine proving a specific in some forms of neuralgia, as the sedative effects of the bromine would be added to the usual action of quinine. The forms of neuralgia in which the latter drug had given best results were those in which evidence existed of malarious or rheumatic influence. In both these cases there was a marked determination of blood to the part, and the periodic dilatation of the blood vessels which occurred in the former varity—every pulsation of which was conveyed to the over-sensitive nerves which accompanied them—was well known. He believed that there was sufficient evidence in favor of the idea that the more prominent physiological effects of quinine were essentially due to diminution of the systemic oxidation which took place under the influence of this drug. It had also been observed to diminish the metamorphosis and elimination of nitrogenous compounds, especially uric acid. The excess of oxygen in the newly described salts would probably act as a beneficial corrective. The capillary contraction which followed the ingestion of quinine promoted the same results as that now described. Dr. Cameron, in reply, said the great point he had endeavored to establish was that the addition of oxygen to the iodine compounds, instead of diminishing, increased their activity.

(To be Continued.)

CORRESPONDENCE.

Carcinoma of the Stomach.

ED. MED. AND SURG. REPORTER:—

I submit the following brief history of a case of carcinoma of the stomach: David Leavitt, American, occupation farmer, aged 44 years. Served as a soldier in the late war. Since his discharge from the service, had suffered more or less continually from chronic gastric and intestinal catarrh. During the last three years of his life, and until within two months of his death, he had received no treatment from the hands of a physician, but had taken a great many different nostrums advertised for deranged digestion. When first called to see him, I found great emaciation. He complained of no pain, save a sense of uneasiness in the right hypochondriac, and oppression in the epigastrium, vomiting, at intervals of twenty-four to forty-eight hours, of great quantities of fluid intermixed with considerable "coffee ground" material. Upon the most careful and repeated examinations no tumor

could be discovered, though the walls of the abdomen nearly approached the vertebral column. There was a pronounced cancerous cachexia, and a diagnosis of carcinoma of the pyloric orifice was rendered. The patient rapidly failed, and death resulted, from inanition. Twelve hours after death an autopsy of the abdominal cavity was permitted. The stomach was considerably dilated; along the upper border of the lesser curvature, extending from the pyloric orifice two inches, there was infiltration of the tissue, feeling rough, knobby and somewhat lobulated; this infiltration also extended through the pyloric orifice, into the duodenum for two inches, completely filling the orifice and intestine. The other viscera were, apparently, free from any cancerous appearance. The pathological condition was regarded as a colloid form of carcinoma. The case is of peculiar interest, from the fact that the most important and almost pathognomonic symptom of gastric carcinoma was absent, the presence of a tumor.

Tracy, Minn. CLAUDE M. FERRO, M.D.

Complete Lateral Dislocation of the Elbow Joint

ED. MED. AND SURG. REPORTER.

A short time back the following case came under my notice: H. C., a large, bony man, was driving a colt to a dog-cart, when the colt shied off to the side of the road and threw him from the cart. In his fall his left arm was caught in the wheel and a complete outward dislocation of both bones of the forearm produced. I saw him about an hour after he received the injury. Having placed him well under the influence of ether, I made a careful examination of the joint, when I found the following condition of things: The radius and ulna were both dislocated from their articulating surfaces on the humerus. The olecranon was twisted around nearly in front of the joint, passing completely over the external condyle, while the head of the radius was dislocated forward and inward, the cup-shaped extremity of the head of the radius being easily felt through the integument of the arm. With the assistance of my father, Dr. Edwin C. Leedom, I succeeded in restoring the displaced bones to their proper position. We were unable to detect any fracture, both bones appearing to be intact. Nearly all the authorities who have written on this subject agree in saying that the most common cause of this accident is a blow upon the inner side of the forearm or the outer side of the humerus, or from the action of two forces pressing upon the arm in opposite directions in close proximity to the joint. A fall upon the hand is said to have produced it, which I think must certainly be a mistake. I do not see how a fall upon the hand could possibly produce such an injury. I can readily understand how it might be produced by two forces pressing in opposite directions near the joint, one upon the outside of the humerus, the other upon the inside of the forearm. But it seems to me that the most usual cause of this injury would be a violent twisting, such as this man's arm received in the wheel, or the twisting caused by revolving machinery. So far as I can learn, a complete internal dislocation has never been recorded. The force applied in this instance must have been very great, and the laceration of ligaments about the joint considerable; nevertheless, the patient made a good recovery, although there is some loss of motion and stiffness in the joint. This case was one of unusual interest to me, not only on account of the rare form of the injury, but because it seemed to me almost impossible that the ulna could be so twisted around without sustaining a fracture of the olecranon; yet such was the case.

OSCAR LEEDOM, M.D.

NEWS AND MISCELLANY.

Preliminary Examinations for the University of Pennsylvania.

In order to facilitate the admission of students and to aid the upward tendency of medical education, the authorities of the University of Pennsylvania have appointed physicians, graduates of that school, in the different prominent cities of the Union, remote from Philadelphia, whose duty it shall be to examine candidates for admission into the Medical Department. The result of the examination is forwarded to the authorities of the University, who, in turn, notify the candidate of his success or failure. By this means the applicant is spared the expenditure of time and money necessary to a trip to this city on an uncertainty.

An Appropriate Reference.

A physician in Texas writes us: "I beg leave to call the attention of G. C. Savage, M.D., of Jackson, Tenn., who gave the profession, in your last issue, his 'discovery that hypermetropia and astigmatism, either alone or combined, are the cause of sick headache and that a properly fitted glass is the cure for it,' to the article of Prof. S. Weir Mitchell, M.D., in your valuable journal, No. 909, August 1st, 1874, pages 81, 82 and 83, also No. 936, February 6th, 1875, pages 101 and 102."

Anniversaries.

April 24th, Prof. Henle, the celebrated anatomist in Gottingen, celebrated his 50th anniversary as physician. Many eminent persons were present. Nearly all Universities of Germany sent congratulations to this rare festival.

April 18th, Prof. von Arlt, the well-known ophthalmologist in Vienna, celebrated his 70th birthday.

Items.

—Mr. T. Spencer Wells, Surgeon to the Queen's Household, has been elected President of the Royal College of Surgeons of London.

—Dr. George J. Grimes, of Columbus, Ga., reports (Atlanta *Med. Register*) a successful ligation of the femoral artery, for traumatic aneurism.

—Two hundred and twenty thousand pounds of quinine are consumed annually throughout the world, about one-quarter of which is used in the United States.

—Japan has now six medical journals published in the native language.

—Dr. W. B. Carpenter, F.R.S., is announced to deliver the next Lowell lectures at Boston.

—Prof. William H. Pancoast has had executed a bust of his father, the late Prof. Joseph Pancoast, for presentation to the Jefferson Medical College.

—The Sultan of Turkey has given a site in Jerusalem for the purpose of erecting a hospice and ophthalmic dispensary, under the auspices of the English branch of the Order of St. John.

—The honorary degree of D.C.L. has been conferred by the University of Oxford on Sir William Muir, M.D., K.C.S.I., Member of the Council of the Secretary of State for India; and Dr. Allen Thomson, F.R.S., formerly Professor of Anatomy in the University of Glasgow.

OBITUARY NOTICES.

DR. DANIEL M. ELLIOT.

Dr. Daniel M. Elliot, of Peabody, Mass., died July 26th, aged 39 years and 9 months.

Dr. Elliot was born at Littleton, Mass., October 9th, 1842. He received his preparatory education at Pembroke, N. H., and entered Dartmouth College, where he graduated, in the class of 1864, at 21 years of age. He was afterwards teacher in the high school at Castine, Me., and also at McIndoes Falls Academy, Vt. He entered Harvard Medical School in 1866, graduating therefrom in the spring of 1870, and returning to his native place, where he commenced the practice of his profession. At about this time he was married to Miss Sarah A. Child. He soon removed from Littleton to South Deerfield, Mass., where he remained until the spring of 1877, when he moved to Peabody, where he continued in practice until his last sickness. The autopsy showed that he died from meningeal congestion with effusion.

It can truly be said of Dr. Elliot, that those who knew him best loved him most. Possessed of a sensitive nature, and of unobtrusive ways, he was not as well calculated for making his way among strangers as many of inferior abilities. He lived a strictly conscientious life; while despising a mean act, no one was more ready to forgive and overlook a fault.

A great loss to those who had chosen him as their family physician; none, however, can feel his absence more keenly than those of his own profession, with whom he was associated.

This world was indeed better because he lived in it. P.

DR. G. EDMUND BREHMAN.

Dr. Brehman died suddenly, of neuralgia of the heart, at his office, in Altoona, Pa., on the afternoon of July 20th. He was born on July 12th, 1846, at McVeytown, Mifflin county, Pa., and was educated at the McVeytown Academy. He read medicine in the office and under the instructions of Dr. A. Rothrock, of McVeytown, and after the full term of study was graduated doctor of medicine in the medical department of the University of Pennsylvania, March 13th, 1869. He located in Altoona in 1869, and after practicing one year removed to Oshkosh, Michigan, where he remained one year and then returned to Altoona in 1870, and has practiced there continuously ever since. He was married April 29th, 1878, to Miss Susan Jessie Smith, daughter of Mr. S. H. and Mrs. Susan A. Smith. Dr. Brehman was a member of the Blair County Medical Society, of the Juniata Valley Medical Association, of the American Medical Association, and of the Altoona Academy of Medicine and Surgery.

DR. J. V. SCHENCK, OF CAMDEN, N. J.

Dr. John Voorhees Schenck, one of Camden's most prominent physicians, died, July 25th, at Atlantic City, of typhoid fever. The deceased was fifty-seven years of age, and was well known through West Jersey, and especially so in Camden, where he practiced his profession for thirty-four years. Dr. Schenck was a son of Dr. Ferdinand Schenck, of Cumberland county, New Jersey. He was educated at Rutger's College, and graduated from that institution as a physician. Afterward he went through another course at the University of Pennsylvania, and graduated from there with high honors. The deceased was to Camden almost what Drs. Gross and Pancoast are and have been to Philadelphia. He was regarded as thoroughly skillful, both as a surgeon and a physician, and enjoyed one of the largest practices in that city.

QUERIES AND REPLIES.

Subscriber.—The directions for changing the old into the metric system will be found in the "Physician's Daily Pocket Record," published at this office.

J. G. K. who has used amyl nitrite for lumbago, as recommended in our issue of July 22d, desires information on the following points, from the readers of this journal who may see it:—

1st. Do not patients find the excessive burning pain caused by the solvent too great to allow the full amount of 10 ♏ to be injected.

2d. What other solvent could be used that would cause less pain.

MARRIAGES.

EVANS—MORE.—On the 18th of July, by Rev. Bishop Simpson, Dr. William D. Evans, of Denver, Col., and Miss Ada J. Moore, daughter of Mrs. E. H. Moore, of Chester Springs, Pa.

RANSOM—BRISBANE—In St. John's Church, Richfield Springs, July 18th, by the Rev. Robert Granger, Dr. George Manley Ransom, of Richfield Springs, and Margaret Lawrence Brisbane, youngest daughter of the late William Brisbane, of South Carolina.

WINSLOW—BISHOP.—On Wednesday, July 12th, at the bride's residence, by the Rev. H. C. Badger, Dr. John Winslow and Mrs. Elizabeth Hamilton Bishop, both of Ithaca, N. Y.

DEATHS.

BRUSH.—At Norwalk, Ct., July 8th, 1882, Francis V. Brush, M.D.

GANISON.—On the 19th inst., at his residence, Newburgh, N. Y., Dr. Isaac Ganison, aged 80 years.

GLENNEY.—In New York, on July 17th, of consumption, Dr. Geo. H. Glenney, in his 41st year.

SCHENCK.—At Atlantic City, on July 25th, 1882, John V. Schenck, M.D., in the 58th year of his age.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

BRIGHT'S DISEASE; PATHOLOGY AND TREATMENT.

BY FRED. HORNER, M.D.,
Of Salem, Va.

According to the monthly reports of the National Board of Health, this malady prevails in country and town, affecting males more than females, at an advanced period of life; indeed, it may be said that granular degeneration of the kidneys is a common disease as life advances. Dr. Mahomed has published a table which shows that in persons dying from all causes, above the age of 50, 62 in 150 have granular kidneys. On shipboard it is rare, because, perhaps, the crews, especially of naval vessels, are recruited and picked men; the officers are not so exempt. For several years past no single neighborhood in the rural portions of Virginia has failed to present examples of the disease in both sexes; the drinking of ice water during the entire year, and of alcoholic stimulants, are considered to predispose to this affection.

For convenience, the subject will be treated under two heads, viz.: First, or the acute form—diffuse nephritis, where the kidney is large, weighing eight to twelve ounces. On section the cortical portion is thick, pale and anæmic, and marked with yellow spots, and the epithelium of the tubes is infiltrated with an albuminoid, granular substance. Hyperæmia is a prominent feature, with congestion of the kidney, which weighs twice or even four times as much as in health. The cortical portion is twice its ordinary thickness. In an excellent monograph, by I. F. M. Geddings, M.D., of Charleston, S. C., "the contents of the tubules are described to be completely converted into detritus, and removed partly by absorption, and in part conveyed away by the urine, and the Malpighian corpuscles are contracted and in a condition of sclerosis. The granulations vary from the size of a millet seed to that of a small pea. The essential character of the disease the learned author considers to be a morbid deposit in the substance of the kidney, attended by an abolition of function, with atrophy of the healthy structure of the gland, the presence of albuminuria, diminished specific gravity of the urine, an altered state of the blood, and dropsical effusion."

The symptoms resulting from the above pathological changes are those of acute nephritis: General ill health, dyspepsia, dyspnœa, palpitations of the heart, frequent micturition, imperfect vision, slight fever, trouble the patient for a long while, and for the relief of which, in the majority of cases, he will resort to empirical remedies.

Second or chronic stage, parenchymatous nephritis: the epithelium of the cortical tubes is thickened and infiltrated with an albuminoid substance in the form of granules, which later are replaced by molecular fat and oil globules. The specific gravity of the urine is considerably diminished, falling from 1.010 to 1.005, with an excess of albumen and deficiency of urea, the latter being detected in the blood. The albumen, which in healthy blood is 65 in 1000, in this disease is reduced to 16 parts. The urine, which amounts in health to 40 ounces in 24 hours, in this disease the patient voids only 12 to 16 ounces.

Examples, however, occur in the advanced stages, in which the quantity of urine is not below the standard of health. The red corpuscles of the blood are sometimes reduced to one third of their normal proportion, and the skin assumes a weaker, cadaveric color, due, it is supposed, to a lack of vigor in the assimilative processes. In the midst of the congested parenchyma is a granular mass, impervious to the finest injection; the outer surface is pale and rough to the touch. The natural structure finally disappears, through absorption, by pressure of the new deposit. Charcot, on examination with the microscope, found the changes to be localized in the convoluted tubes; "the tubules are blocked by the deposit of fibrine plugs, and the color of the kidney is yellowish and gives to the organ a granular appearance." The effect upon the urine is claimed to consist in the diminution of its quantity, in the presence of albumen, and in the deficiency of urea and saline matters, in consequence of which the serum of the blood with its albumen passes readily, while the saline matters and urea are checked. Dropsy is an associated disease, and when present with the symptoms of granular degeneration of the kidney, there can be no further doubt as to the nature of the affection. An anæmic condition accompanied by organic disease of the heart and lungs are sure precursors of a fatal result. Out of 100 cases recorded by Dr. Bright, there were only 27 in which no cardiac disease could be detected; in 52 there existed hypertrophy; in 18 valvular disease, and in 11 the aorta was affected, all of which were considered to be due to the existence of anæmia.

The chronic vomiting which attends the closing scene he refers to the cardiac affection, and is merely functional. In a late number of the *Lancet*, Robert Sandys, M.D., discusses the influence of Bright's disease in developing latent valvular disease of the heart, and assumes that a common cardiac lesion is dilatation attended by a systolic mitral murmur, succeeding an attack of rheumatic fever." This author further asserts "that chronic Bright's disease is a cause of atheroma of the aorta and of the aortic valves."

As in the acute stage, so also in the chronic, the true nature of the disease may, for some time, be undetected. An early symptom of chronic Bright's disease is amblyopia and other derangements of vision, along with obscure lumbar pains, and pallor of the complexion, presenting a peculiar, ashy whiteness; the features appear blighted and the hair changes its natural color to the premature hue of old age, which, with the existence of tube casts and albumen in the urine, may be assumed to be invariably pathognomonic of Bright's disease. Here it may be added that the proper method for testing the urine, *e. g.*, with heat, if the phosphates are suspected to be present with albumen, nitric acid should be added to redissolve them. If the urine be alkaline, heat will fail to coagulate the albumen, unless the alkalinity be removed by a few drops of acid.

Treatment.—The fact that congestion and hyperæmia of the kidneys, with severe pain, and fever in the acute stage of granular degeneration exist, would be suggestive of the judicious use of local depletives to the lumbar region, dry or wet cups, anodynes, and active but not drastic purgatives; for example, the solution of citrate and bitartrate of potash combined with a few drops of dyalised iron. Active medication is not so important as attention to diet; rest, healthful recreation, and travel, and what is now esteemed to be a sina quo non, prompt resort to suitable mineral springs or the use of the waters which have proved by experience to be beneficial if not actually curative.

By way of illustration of the treatment of the chronic form of Bright's disease, the following details of a case successfully treated may be given: Dr. Henry Frost, late of Charleston, S. C., invited me to a consultation with him. The patient was a man of 50 years old, the son of a physician, in early life was thriftless and dissipated, and for several years past had complained of general ill health, dyspepsia, shortness of breath, and palpitations of the heart. During the spring of 1881 he suffered from an attack of nephritis. On examination the urine was found to contain albumen. For this affection he had been appropriately treated by Dr. Frost. In the month of June the cardiac distress was increased, œdema of the eyelids and right leg was observed, accompanied by nausea, severe pain in the hypogastrium, diplopia and slight amaurosis. Six weeks later there was general dropsy of the abdomen and inability to lie down. Epsom salts, ℥ iss, dissolved in a quart of water, in the quantity of a wineglassful, was administered three or four times daily; also

℞. Fluid extract jaborandi, gtt. x
Tinct. digitalis, gtt. xv.
Ter die.

The fluid extract jaborandi caused nausea and was suspended. Emulsio balsam copaiba and tolu, with muriated tincture of iron, were substituted for it, and continued for several weeks. The dropsical fluid was discharged from the legs, after acupuncture, by the gallon, during his illness, and painful

sores and hemorrhoids contributed to the distress of the patient; nor did he escape from the dangers incident to so serious a disease and its complications. At times was delirious and comatose, and presented all the symptoms of uræmic poisoning. He was rescued more than once by the prompt use of large quantities of alcoholic stimulants, and careful nursing day and night. His diet was skimmed milk, fresh meats, fruits, etc., especially grapes, and the use of Buffalo Lithia water, from spring No. 2. Under this treatment the dropsy of the abdomen, legs and face began to disappear. The patient was then given "alum and iron mass," prepared by Landrum & Litchfield, druggists of Abingdon, West Virginia. This salt was given with reference to its tonic and astringent properties, and contributed to improve the digestion, to promote absorption, and to restore the properties of the blood. By the month of October this patient recovered sufficiently to travel and visit a brother residing in the city of Richmond. There he was submitted to the care of Dr. W. B. Gray, who instituted, I am informed, the following treatment, for the sequelæ of the case:—

℞.	Rad. scillæ,	ʒ ij
	Tart. ant. and potass.,	gr. j
	Potass. sulphatis,	℥ ss
	Potass. bitartratis,	ʒ iss.

Teaspoonful three times daily.

For the relief of the cardiac symptoms—

℞. Tinct. veratri, gtt. iv

ter die, was also ordered. He was also advised to use the waters obtained from the New Kent mineral springs, containing lithia; they are generally prescribed by the physicians in Richmond.

During the month of November this patient returned home, his dropsy entirely cured and not a trace of albumen in the urine. At the present time, on careful physical examination, he may be pronounced relieved. His complexion, appetite and strength mark the well man. The urine has resumed and retains the healthy character, is normal in quantity and specific gravity.

For the encouragement of such a patient, the opinion of G. B. Wood, M.D., "Practice of Medicine," may be quoted: "I have a distinct recollection of two severe cases of inflammatory dropsy, with strongly coagulable urine, of which one occurred nearly twenty and the other thirteen years since, and both perfectly recovered without subsequent relapse." Other later and eminent authors are of the opinion that dropsy dependent on Bright's disease is prone to recur.

THE INNOVATIONS OF MEDICAL AND SURGICAL PRACTICE.

BY J. M. F. GASTON, M.D.,
Of Campinas, S. Paulo, Brazil.

(*Concluded from p.* 201.)

This naturally brings up the mooted point of the "survival of the fittest" ligatures, as, after all the experiments of silk, metallic, catgut and caoutchouc loops for securing arteries and pedicles, there seems to be a tendency to settle down upon the silk ligature as affording all the requisite conditions for security and freedom from undue irritation, with a remote prospect of final absorption. It is calculated to puzzle the inquirer after the stable and trustworthy in surgical appliances, to note the vacillation of high authorities in regard to this apparently simple practical selection of a ligature; and while it is commendable to try all and hold fast to the best, we cannot, if we would, forget the splendid tribute of Dr. J. Marion Sims to the silver wire ligature, in his address, some twenty five years ago, before a distinguished audience in the city of New York, upon his first presentation of his improvement in operating for vesico-vaginal fistula to the medical men of that city.

His claims for this mode of ligation have not been belied by subsequent experience; and it is a matter of surprise that with its invariable good results and its capacity to remain encysted in any order of tissues, there should be a disposition manifested to abandon it for the doubtful recourse of other means. I recall vividly the fact of testing the silver wire suture about the time it was brought so prominently to the notice of the profession, in reuniting the tract of the small intestine after three pieces of eight or ten inches had been cut away, by a man under the influence of delirium tremens, in Columbia, South Carolina, and the happy result in saving the life of the would-be suicide, the perpetrator of this act of desperation. Since that time it has been used by hundreds, and even thousands, with like salutary results, in all varieties of cases, without disappointing their legitimate expectations in a single instance.

As the applications of elastic ligatures are thus far limited to special conditions, and for the most part to effect temporary constriction, this mode of ligation may be considered *sub judice* on the part of surgeons. It is an innovation that promises to accomplish what none of the others can claim to do, in affording a steady and graduated compression upon the included tissues, without risk of laceration or cutting the texture of such parts. If we are to accept the high au-

thority of Olshausen, the elastic ligature, "when left in the abdomen, after having buried itself deeply in the tissues, becomes encapsulated and harmless." Others have applied it to the pedicle after the excision of various parts, and with invariable good result; so that its extension to the ligation of large vessels generally seems to be warranted; and it may be inferred that a simple elastic ring should prove adequate to the necessary constriction of the umbilical cord, thus obviating a not infrequent accident of secondary hemorrhage from the cutting of its soft substance by the ordinary mode of ligation.

The caöutchöuc tube presents special advantages in cases requiring a uniform compression; yet the round solid cord or flat strips of this material are applicable in a great variety of circumstances demanding a ligature, and if we can rely upon the tolerance of the vital organization for retaining this vegetable substance without giving rise to any irritation or suppuration, the application of the elastic ligature to the arteries in amputations admits of the flaps being closed up at once throughout their entire extent, thus securing complete occlusion.

That restless desire for change has led to multifarious trials of other materials, yet it is, of all, perhaps the very best thing which can be left in contact with the susceptible tissues of the human organism in the form of suture or ligature.

If Mr. Bryant's recommendation of torsion of arteries, without ligation, is sustained by more enlarged experience, the arrest of hemorrhage is settled for all time, and it should be hailed as the greatest advance in modern surgery.

This simple process has long been applied to small arterial twigs when divided in the course of an operation, but this bold proceeding of arresting the flow of blood from a large arterial trunk, such as the femoral, and relying upon torsion alone to secure the closure of the vessel is, so far as I am informed, a novelty, whose reach can only be appreciated by those who know the real difficulties connected with the application of ligatures to the main trunks of the arteries. It is claimed, and sustained by reference to cases, that when the proper tissues of the artery are twisted eight or ten circuits upon its own axis, no blood will be lost, either primarily or secondarily, and that there is no sloughing of the extremity upon which torsion is thus executed.

In view of the representations as to the favorable results of this process in the hands of Dr. Bryant, it would seem that surgeons are authorized to put it into practice; yet it should be used with all the conditions and precautions under which it has been performed by that distinguished operator; and it is especially inculcated that the artery shall be detached from its surrounding investment, and drawn out, preparatory to twisting the extremity. Should this be done in a bungling manner, and serious consequences ensue, it would bring discredit upon the operator, and I take it that any one undertaking this process upon the femoral should not only be especially careful in the observance of the details in performing it, but should be extremely watchful of the case for several days subsequently; watch and wait, in faith.

The transplanting of tissues is no longer limited to removal of the skin from one part to another of the same individual, or from the living body of one individual to that of another person; but the skin has been removed from the dead body several hours after life was extinct, and transferred to a living being, with reproduction of vitality in that portion of the cutaneous investment so transplanted. It has likewise been demonstrated that ossific matter may be engrafted upon the bony structure, being taken from the same or a different individual. Thus deficiency of bone has been supplied, and it is within the scope of surgery to replace segments of necrosed shafts or to supply the substance that may be lost in resection of the bones of any part of the body. Artificial joints, resulting from degeneration of ossific deposit in cases of fracture, have thus a reasonable prospect of relief, maintaining the entire length of the member; and in like manner it may be anticipated that the aperture of the cranium resulting from the operation of trephining may be closed. If the cutaneous substance can be taken from a dead body, as has been demonstrated, and regain its vitality by contact with living parts, there cannot exist any insuperable difficulty in the transfer of a section of bone from the head of a decapitated culprit or from one that is hanged, to the cranium of a living subject, so as to fill up a vacancy that may exist. The occasion for such an operation may be opportunely selected, as it is not requisite or desirable that it should be done at the time of the trephining of the cranium, but subsequently, when the scalp may be reformed.

The audacity of practical innovation is not exhibited in anything more strikingly than in a case reported by Rosenstein, of Leyden, in which the pericardium was laid open and two drainage tubes inserted into the cavity of the sac, with the restoration of the patient, after four months of this treatment, for a purulent effusion. It was not enough that this investment of the

citadel of life should have been invaded previously by the aspirating needle, but this daring pioneer has ventured upon the far more perilous undertaking of drainage from its cavity, and with a salutary result. It would really appear that surgeons of the present day are actuated by sentiments very similar to those venturesome heroes who, during the last quarter of a century, have been striving to reach the North Pole; and the ultimatum with each is, who can go furthest!

An old idea has been recently revived, with more zeal than discretion, in seeking to supply the deficiency of vital fluid by the transfusion of the blood from one to another, or the introduction of defibrinated blood, milk, or the saline solutions into the veins or arteries, and likewise by the injection of blood into the peritoneal cavity. It has been also gravely claimed that, independent of any lack of blood for the nourishment of the body and the performance of the ordinary vital functions, in cases of mental derangement, the blood of the subject of lunacy may be removed and replaced with healthy blood, with decided advantage to the sufferer, and that the experiments made have given encouragement for their repetition. The absurd denouement of the experiments and deliberations upon the various articles adapted to replace or modify the natural production of the vital fluid is a preference for simply diluting the blood with a saline aqueous solution injected into the venous circulation. Why might not this same end be well reached by filling the colon with the said solution and leaving it to be absorbed, or to effect the desired modification by the process of endosmose and exosmose through the coats of the large intestine, and thus altogether obviate the risks of introducing the fluid directly into the circulation.

The proceeding most in conformity to a natural process for replacing the lost fluid would seem to be that of transfusion from the vein of the arm in the person supplying the blood to a corresponding vein in the person who is to receive it, maintaining the temperature in the passage and securing against any contact with the atmosphere. It is thus and thus only that a removal of the circulating fluid without material modification can be effected; and if it should be my misfortune, by any accident, to lose such a quantity of blood as to endanger the recuperation of my forces, I should risk this in preference to the other measures which have been suggested for replacing the blood. In the transfer of blood from one body to another, there should, of course, be observed all the precautions possible to secure correspondence in the quality of that supplied to that lost or to the remnant for augmentation.

The outstretched arm of aggressive, and if we may so style it, progressive surgery, has laid a violent hand upon the liver, and seized especially upon the gall bladder for a trial of skill and daring interference with its disorders. Although the results thus far have not given assurance of final triumph, enough has been accomplished to embolden others to hope for success, and with the advancements in abdominal surgery, it should not surprise us if dilatation of the ductus choledochus should be effected by an opening into the duodenum; or if this tract should be obliterated, there should be maintained a direct communication of the gall bladder with the intestinal canal by uniting them with sutures after making the requisite orifice in each for the passage of the contents of the gall bladder. We know already that an ulcerative process has accomplished this communication in entire obstruction of the gall duct, and I have good and sufficient reason to believe that a patient of mine has realized this abnormal change, and is now in the enjoyment of a fair measure of health. It must be taken for granted, in this case, that my diagnosis, made while the acute symptoms were present, and given to a colleague who was in attendance with me on the patient, was correct, as there can be no opportunity afforded for verifying it, except by a post-mortem examination. In view of the probability of a restoration of the bile to the alimentary canal, an operation to effect this union promises far better results than the fistulous discharge of the gall bladder externally.

The hydropathic treatment of pneumonia, croup, etc., has been heretofore confined to specialists, but some prominent members of the medical profession, being actuated doubtless by the sentiments of the pastor who declared that the devil should not have all the good music, have experimented and approved the water cure in various affections. With the recommendation of Dr. Austin Flint, and the detailed observations of cases treated in this manner, there cannot be a doubt of the safety and efficiency of the application of towels wrung out of cold water to the chest in pneumonia. We have ample testimony from Germany and other parts, of the advantages of cold baths in fever, and in all cases of elevation of the temperature of the body. This practice is not by any means recent, yet its recognition and adoption by the profession in this country is a novelty, so that it is entitled to consideration under this head of innovations. I have no

sympathy with that hide-bound policy of rejecting any course of treatment, because it has been resorted to by quacks. Let us profit, if possible, by even the rash experiments of the empiric, and cull from the vast field of tares the little sound grain that might be useful to us in treating the "ills to which flesh is heir." The botanic practice of Thompson, though false in theory, brought into notice the properties of some important articles, and among them, the great virtues of lobelia inflata and the capsicum annuum, by which the regular profession has profited vastly. The s eam vapor bath and the enveloping in blankets, which were used, or rather abused, by the disciples of the said Thompson, enabled judicious observers to turn to account that part of the practice which proved to be efficacious, so that a benefit was unwittingly thus conferred by these experimenters upon the resources of art and nature without regard to science.

We must not even ignore the negative results of homœopathy in leading to a just appreciation of the vis medicatrix naturæ, and hence to the adoption of the expectant masterly inactivity in some forms of disease. This delusion is simply the shadow of nothingness, and should rank in the scale of curative means not as zero, but really as "naught without the rim," or as a minus quantity in the estimate of resources in the treatment of any disorder of the human organism. How it has happened to have adherents among intelligent people is totally incomprehensible, except upon the principle that "if it does no good, it does no harm to the organization, and serves as a toy to tickle the fancy.

The prevailing spirit of active interference in the practice of medicine, and of operative procedure in surgery, needs, perhaps, to be somewhat curbed by a little patient watching of symptoms, and we have learned, by the manner in which "diseases drag their slow lengths along," under the time serving ordeal of expectancy, that no serious trouble ensues from some disorders by this delay in the application of energetic means of treatment. This course could not be applicable to all cases, as there are diseases which exact the earliest and the most stringent measures to arrest their development. This aggressive policy recommends itself whenever the way is clear for action, and whatever our hands find to do we should do it with all our might. Caution in diagnosis and boldness in practice are the watchwords of the intelligent physician and surgeon, and generally lead to success. The axiom of Napoleon, that providence was on the side of the big guns, denuded of its sacrilege, is eminently applicable in the treatment of all diseases which require interference, and the doses of medicine or the extent of cutting should be proportioned to the gravity of the evil to be remedied. Risk of killing a patient by medicine or with the knife is sometimes warrantable, rather than leave him to a certain fatal end by disease; and the physician or surgeon who fails to afford the only relief that is practicable, through apprehension of the judgment of bystanders, is justly chargeable with neglect of duty. Let us suppose that we have a case of intussusception that is clear and well defined, which has resisted all the medication possible, with the certainty of a fatal termination if not speedily relieved, and what is indicated in view of the advances made in our resources at the present day? It is beyond a question that the abdomen should be opened, and the site of the occlusion being ascertained, an attempt should be made to withdraw the part of the intestine that is confined by the exterior portion; and this being impracticable, from adhesion or from the closeness of the stricture, excision of the segment should be resorted to, and the free ends united by silver wire sutures in the margins. Death may ensue, notwithstanding this is done with every possible precaution; yet death must certainly occur without it, and we should give the patient this chance of escape. The fatal procrastination in deferring this procedure until such vital depression has resulted as to preclude restoration, is certainly culpable; and hence in this, as in strangulated hernia, delay is always a dangerous practice. To perform an operation upon a moribund subject can rarely ever be justifiable; but when, by a timely resort to the knife, we choose the less of two evils, it is commendable to literally cut the Gordian knot.

This principle holds good in all branches of practice; and we thus endorse the sentiment that the "bravest are the tenderest;" for it is a true regard for the welfare of the sufferer which actuates the operator in such a case.

In critical conditions critical remedies should be resorted to, both by the physician and by the surgeon; and no half-way measure of compromise is suited to the circumstances of gravity which are threatening the life of the patient.

Should it appear that the heroic interference which characterizes the practice of some of the medical profession in this progressive age is rashness, I venture the assertion that before the close of the nineteenth century the daring intrepidity inspired by further investigation will have so far outstripped anything yet accom-

plished, as to cause the advances of to-day to appear tame, from over caution in executing what is imperatively demanded in emergencies; and cautious boldness must triumph over disease.

The lesson to be learned from this desultory consideration of the present status of practice in the medical, surgical, gynecological and obstetric departments, is that of encouragement in ascertaining the capacities of the human organization to admit of the requisite explanations of its disorders, and to submit to the curative processes which are indicated for their correction. The extravagances of novel measures of treatment will ere long disappear, under the crucial test of experiment; and careful investigation should confirm the tentative expedients which have been dictated by a proper appreciation of surrounding circumstances. Statistics must furnish the mirror in which the profession shall discover the defects of erroneous theory and injudicious practice, so that with elaborate reports of cases treated, we have a sure guarantee against vicious proceedings for the future. With the initiation so conspicuous in the recent developments of thought and action, it devolves more than ever upon observers to record the results which are presented, and especially is it incumbent upon those entering new fields of inquiry to note minutely all the data of the preliminary condition, progress, termination and consequences of the disorder. The antecedent and subsequent state of a patient are important elements in the study of a disease, and of still greater moment in the history of a surgical operation. If these off-hand comments upon passing events seem to attract the attention of the profession to the necessity of due circum spection in all things, the end in view will have been attained.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINIC BY ALONZO CLARK, M.D.,
Professor of Pathology and Practice of Medicine.

Bright's Disease.

First patient, a male, about fifty years of age. He states that he has been confined to the house about four months; that he has to stagger from one place to another across the floor, but that he is better now. The feet are swollen; much less, however, than they were previously. He prefers to lie on the left side at night, which may account for the fact that the left leg is swollen more than the right. The leg pits deeply. He also complains of having pain in the back. This symptom, with the weakness in the limbs which he complains of on walking, would suggest spinal disease. I have known persons with the legs considerably swollen. They could walk well enough, but when they got on the bed they could not lift their legs up. This patient says such has been his case also. That, probably, is the explanation of his awkward movement, especially as he has had no paralysis anywhere else. It is true he thinks the sensation in his legs is considerably diminished, but when I pinch him he grumbles.

Then the question is, what is the cause of the swelling of his legs? That is the most marked feature of his case. The answer naturally is, kidney disease; but Dr. Wheelock informed me that he examined the urine and did not discover albumen. That may be; for persons sometimes come to me saying they have Bright's disease, been so called by their family physician, and I examine the water and find no albumen. I do not conclude that they have not Bright's disease, but continue to examine it every second or third day for three or four weeks, because I know the microscopic, the chemical and the clinical symptoms are often absent for two or three weeks in a case that is really confirmed, and then will come again. The fact, therefore, that no albumen has been found in the water is by no means conclusive, especially when we have the evidence of the œdema. The œdema has been confined mostly to the legs and feet; he says he has not had any swelling of the hands.

There is an early sign of coming œdema that is, however, fallacious as a distinctive sign. I refer to the tear line. A little œdema will come on the conjunctival membrane of the lower lid, and pressing the lid against the eye, will force it up on to the top of the lid, and it will then have a little wire appearance, or the appearance of a small thread running along the lower eyelid. This patient has that. There is a little œdema of the conjunctiva elsewhere also. It goes away when you lift the lid, but comes again immediately after. He says there has been no enlargement of the abdomen.

He has had trouble in going up stairs during the last week or two, but it seems to have been due principally to the condition of his legs. He says he does not get out of breath except on some exertion.

We will examine his chest and abdomen. The fact that he prefers to lie on the left side is rather evidence against cardiac disease. Persons who have much of that trouble are very apt to lie upon the right side or back. I do not get any signs of valvular lesion about the heart, although there is a little hypertrophy of that organ. There is no pain in the chest. There is dullness behind, over the lower portion of the thoracic cavity, indicating a little fluid in either pleural cavity. There is, you will observe, some œdema of the face and swelling under the eyes.

I think this is an instance in which it is safe to infer that there is some trouble with the kidneys, and that, at the present time, conclusive evidences are not apparent, but perhaps a week hence it will be different.

With regard to the treatment in such a case, the great point is to keep himself warm. If he

is obliged to go out in cold weather, he should protect himself with an abundance of clothing. If he is not obliged to go out, it is better, in cold weather, to keep in the house. I have kept such patients in the house all winter, and directed them to keep the temperature of their part of the house at 72° F., night and day. Not so particular at night, because the bed clothes will protect them, but it is better to have it uniform. This man cannot do that; he will have to protect himself as much as he can in cold weather by clothing. A steam bath is a very excellent thing, to be taken twice a day, and anybody can arrange a home apparatus for that purpose. It may be prepared by taking a tin can that will hold a couple of gallons of water, covered with some utensil; put a tube in the dome of it; connect with this tube another one, six feet long, having an angle, which will convey the steam to the wooden chair on which the patient sits while covered with blankets, fastened about the neck. In a few minutes the patient will begin to perspire, and this may be kept up say twenty minutes or half an hour, when he should be well rubbed off, and if it be in the evening, as I generally direct, he should put on his night clothes and go to bed. If he sweats a little after that, all the better. Then in the morning before he gets out of bed, he should be rubbed thoroughly with a dry flannel so as to stimulate the circulation. That stimulation of the circulation of the skin with dry flannel or some agent that is equal to it should be practiced every day, whether he takes the bath or not the night before. I was in consultation near here some years ago, and it was agreed that to sweat the patient was desirable, and we were devising a plan by which it could be carried out when the nurse asked what was wanted. It being explained to her, she said she could do that. Boil a peck of potatoes; wrap them in a cloth and lay them close to the body. She did so, and it worked very well. It is often the case that bottles of water, not exactly hot but pretty nearly, are enveloped in damp cloths and laid alongside the body. The œdema will sometimes disappear on the use of these steam baths, but commonly it is necessary that some diuretic be used to accomplish that. All effusions that are observable in the body are easiest carried off by the kidneys, disturbing the system less than if carried off by any other emunctories that are capable of doing it.

For him, probably, as good a diuretic as any that can be prescribed is the sal diureticus, the acetate of potash, twenty grains every two hours, in water; and the infusion of digitalis, commonly a dessertspoonful, or two drachms, will be enough, taken three times a day. He cannot conveniently take it with the salt, because he takes that every two hours.

Facial Paralysis.

Case 2.—This man complains of a disfigurement of the face. He works by night and sleeps by day, and about two weeks ago, having gone to bed perfectly well, he awoke, and observed that the right side of the face was paralyzed. The right eye watered. No pain was felt, but the face appeared disfigured.

This kind of deformity, paralysis, often comes of inflammation of the theca of the seventh nerve, the portio dura, and in that case leeches are the quickest remedy that we can use, applied as near to the source of the nerve as can be done; but in this case there is no tenderness at all. I press pretty hard, to the extent of a couple of pounds weight, and he says it does not hurt him any. This is not a very uncommon affection, and it generally comes just as in this man's case; it comes in the night, and I think it is more likely to occur if there is a draft of air upon the side of the face corresponding with the paralysis. Many of these cases will be relieved without any remedy in the course of four, five or six weeks. In others it is of very considerable duration; indeed, in some it is not relieved at all, being carried for years. Relief, when it is effected, is obtained from various sources; sometimes from electricity. Medicine, I think, has no power over it at all; at least I know of none. As just said, electricity seems to be remedial in certain instances. Dr. Detmold, some years ago, invented a little electrical apparatus which he thought would act well in these cases, and I think it does. It is a compound metal wire, containing two metals that act upon each other in a way to produce electricity. At one end is a hook which goes in the mouth, lifting the angle of the mouth up on the affected side, and at the other end is a hook that goes over the ear. He has the patient wear that continually, except while eating. It is a simple apparatus, and the saliva of the mouth probably aids in making it electrical.

You observe, as the patient smiles, how the face is drawn to the left side. There is no affection of the tongue that I can see. He can chew his food all right on either side. Sometimes the paralysis is so positive that the food will come out of the mouth when he chews with the teeth of the affected side, but it does not seem to do so in this man's case. I see some movement of the muscles of the paralyzed side, as he talks, which seems not to be entirely passive.

Spinal Sclerosis.

Case 3.—Our next patient is a man about thirty-three years of age, who, as you see, has been led into the room by his wife. She says he has been sick about two years; has not been able to walk for about a year and a half. He has cramps; sometimes unconscious four or five hours after the attack. In the attacks the arms and legs are straightened and shake. The hands are clinched, and he attemps to get out of bed; talks, but appears to be unconscious. After the attack he asks what had been the matter, remembering nothing that had occurred.

Some of these symptoms point to epilepsy, while others do not. It is not uncommon that persons after an epileptic attack are really delirious, sometimes for half an hour, sometimes for four, five, or seven hours. She says he is white during the attack, which would not point to epilepsy.

Some days he cannot walk at all, and you will observe that muscular paralysis is plain enough. The next point arises, is there paralysis of sensation. Not being provided with a special instrument to test the sensation, we will take a card that will hold firmly pins stuck through it,

putting the pins two or three inches apart, to begin with, and reducing the distance gradually as we test his sensation.

You will observe that there is no defect in the sensation in his case. We would infer that there is here thickening of the posterior column of the spinal cord and not of the anterior. This is not a very uncommon form of sclerosis. He has not the walk of locomotor ataxia, but his wife's description of his walk formerly corresponds to the walk of that affection. We may infer, then, that he really had locomotor ataxia, and that it is now being converted into paralysis. We have such a patient in the hospital at present, who was treated in a variety of ways, by medicines given internally, until we finally settled down upon the fluid extract of ergot, increasing the dose until he got to taking a drachm three times a day. He continued that an entire year, at the end of which time he was so far restored that he could take the place of orderly about the wards. He has now been in the hospital five years, and some of the Professors show him to the students every year.

Now, as an encouragement in this case I should think the same medicine would give some relief to this man. Dry cups might also be applied over the spine, as it can be done by some one of the family, by burning a piece of paper in a small-sized tumbler, placing four on the back, two on either side of the spine. This, with the fluid extract of ergot three times a day, would be the treatment. I would not start out with a drachm of the medicine, but half a drachm, and see if he bears it fairly. This reminds me that we now have in the hospital a man suffering from dry gangrene of the toe. The pulse is good, and there is no obstruction in the arteries. We learned, after he had been in the hospital a day or two, that he had been eating rye bread; that for years he had eaten it whenever he could get it, and living in the west he could generally get it easily enough. The question presented itself before us whether this dry gangrene was the result of ergot which he got in the rye. In times past, when rye was used a great deal, dry gangrene occurred which was attributed to the rye, not, perhaps, to ergot which it contained, for that was little known until about the time of Dr. Stearns. But I am not sure about the agency of rye bread in this case of dry gangrene of the toe.

Graves' Disease.

Case 4.—Here is a case that you will be interested in. You will observe, first, that there is swelling in the neck. I have not seen her before, but the case struck me in an instant as she entered. Second, there is some degree of prominence, not remarkable, of the eyes. And third, I suppose we shall find the pulse beat at the rate of 120, perhaps beating more rapidly than under ordinary circumstances, coming into a room where there are so many strange faces. But I do not find any pulse beat at all, either at the wrist or elbow. The heart beat, however, is strong enough, and exactly at the rate of 120. The hands are warm enough; I do not know why the pulse cannot be felt.

She has, then, three elements of what is sometimes called Graves' disease, because he described it before anybody else, in the English language. It is claimed for Basedow in Germany, and for Trousseau in France, but Trousseau acknowledges that Graves described it before, so that it is not very wrong to call it Graves' disease. The thyroid gland is swollen, the right side more than the left, in this case. It is a mild case, showing the three characteristic features of it in a limited degree only. Congestion produces these swellings in the thyroid gland and behind the eye. How it should fall out that three parts of the body that are at a considerable distance from each other should undergo the same change, and the intermediate parts not be affected, is a matter difficult to explain. Still, case after case presents itself, though it is a rare affection, and we are obliged to assume that Graves was right in associating the three congestions (he did not explain it, however), and that it makes really one disease.

The patient says her general health is good; she eats well, digests well, has no pain. She does her housework and thinks she is as well as usual.

You ask what would I prescribe? That same fluid extract of ergot, because of its effect upon the capillaries. I would have her begin with twenty drops, increase it to thirty, forty, and perhaps, to fifty, in a week or ten days, and if it works as well as it has done in some of the cases I have seen, she will be improved in a moderate length of time. Speaking from my own experience, it always gets well; but I notice in the records of other persons it does not always. At any rate, there is hope for improvement in this case, as it is not a very well developed one. It has these three features, but none of them marked in a high degree.

Medical Societies.

THE RECENT EPIDEMIC OF MEASLES.

BY J. T. ESKRIDGE, M.D.,

Physician to the St. Mary's and Howard Hospitals.

Read before the Northern Medical Society of Philadelphia, June 23d, 1882.

The severity of the recent epidemic of measles is of sufficient interest to occupy the Society's attention for a short time.

Case 1.—Charlie, aged ten years, moderately strong, suffered from scarlet fever and some of its sequelæ (otorrhœa and renal dropsy) three years ago, and from a moderately severe attack of pertussis attended by bronchitis, with some pulmonary collapse, during January and February of the present year. After this he was quite well until April 21st, when he complained of headache and sick stomach. His temperature at 2 P.M. was 101°; pulse 130 and vibratory; respirations 28 per minute. During the afternoon he felt chilly. His bowels were constipated. Eyes and air passages were in nearly normal condition.

22d. Morning temperature 98°; pulse 96; respirations 24. He did not feel sick, but his pulse was still irritable. Malaria was suspected and he was accordingly treated. I did not see

him the next day, but I learned that he had been feverish during the afternoon.

24 h. Afternoon temperature 102°; pulse 130; respirations 30. The eyes were watery, conjunctivæ injected, nose discharging freely, throat sore and inflamed, and attended by a troublesome cough.

25th. Morning temperature 102.8°; pulse 135; respirations 36. Face quite red, with a scarlet-fever like rash. At 2 P.M., temperature 103°; pulse 140; respirations 40. The pulse was extremely irritable. His throat was very much inflamed and a papular eruption covered the buccal mucous membrane No false membrane formed on the tonsils or fauces, but the parts were of scarlet redness, and so painful that swallowing was difficult. A measley eruption covered the body and limbs. The heart's action was labored, and a systolic murmur was heard at the apex. During the afternoon and evening broncho-pneumonia began to develop, which resulted in partial consolidation of the bases of the lungs. Soon his breathing became rapid, and he irritable and restless. At times, when delirium was most marked, it was difficult to keep him in the recumbent posture. After the cardiac area and the surface over the involved portions of the lungs were dry-cupped and counter-irritated with mustard, the chest was kept wrapped in an emollient poultice, which was renewed every three or four hours. Carbonate of ammonia and small doses of aconite were given regularly at short intervals. He had taken no food during the last few days, and now could not be persuaded to take more nourishment than small quantities of milk to which a little brandy had been added.

26th. Morning temperature 102.5°; pulse 136; respirations 44. Urine scanty and high colored, but contained no albumen. No change during the afternoon.

27th. Morning temperature 102°; pulse 130; respirations 40. Slight improvement since yesterday. He continued in nearly the same condition during the following two or three days, when he began to gradually improve, his lung and heart troubles not entirely passing away until nearly three weeks later. After the chest troubles developed, the eruption on the skin became much darker, and was more tardy than it is usually in fading. The face contained no measley eruption, but the rash here presented the appearance found in a typical case of scarlet fever, with the exception that desquamation was not complete. At the height of the disease inflammation attended by suppuration of both middle ears manifested itself.

On June 13th, the left ear had regained its normal acuteness of hearing, but that of the right ear was still somewhat impaired. The eyes were the seat of acute phlyctenular conjunctivitis, but the corneæ and deeper structures were uninvolved. The urine remained free from albumen throughout the attack. During the first five or six days of his illness he ate very little. He is to-day, June 23d, quite well, except a recent attack of bronchitis.

CASE 2.—Mamie, a bright and vigorous girl, ten years old, enjoyed excellent health until her present illness. She was the third and last, in a family of three children, to contract measles. A sister, three years younger than herself, had, the early part of May, of the present year, a moderately severe attack, attended by considerable laryngitis and bronchitis. The recovery of this sister was rapid, uninterrupted, and complete. The youngest sister was attacked by measles one or two days before the eldest, and suffered quite severely from laryngeal, bronchial and conjunctival inflammation. The parenchymatous tissue of the lungs was but little involved. This one, too, made a good recovery after a rather tardy convalesence, the eruption being a little darker than usual, and remaining visible more than a week longer than we commonly find in this disease.

My attention was first called to Mamie's condition, May 17th, three days after she had first complained of feeling sick. Her eyes were watery and conjunctivæ injected; temperature 102°; pulse 130; respirations 32.

18th. Morning temperature 102.5°; pulse 134; respirations 36. The eyes were quite red, conjunctivæ ecchymotic, and nose discharging freely. A constant laryngeal cough annoyed her. An eruption was just beginning to appear on the face. Evening temperature 103°; pulse 136; respirations 36. Bleeding from the nose frequent during the last twenty-four hours.

19th. Morning temperature 102°; pulse 130; respirations 32. The face was completely covered by a measley eruption, which had almost entirely spread over the body. She was not troubled with cough, but was feeling well, although she had eaten nothing during the last four or five days. Nose bled freely several times during the night. Evening temperature 104.7°; pulse 148; respirations 64. The pulse was small and exceedingly irritable; breathing short and labored. A hacking cough, which the mother said began at 5 P.M., was now very troublesome. Her feet and hands were much cooler than the other portions of her body. Percussion resonance over the bases of the lungs, posteriorly, was slightly impaired, and numerous crepitant and subcrepitant râles were heard throughout the chest. Vesicular breathing was lessened in the lower but increased in the upper portions of the lungs. The heart was acting tumultuously, and the sounds were so indistinct that clotting in the right ventricle was feared.

The physical examination of the chest, when taken in connection with the temperature, pulse and respiration, showed that acute and violent congestion of the lungs and bronchial tubes had taken place. It was evident that unless the onward march of the disease was speedily checked acute œdema of the lungs, or capillary bronchitis, complicated by pneumonia, might terminate the little sufferer's life.

The chest was thoroughly dry-cupped, and sinapisms, followed by a poultice reaching from the second to the twelfth ribs, and encircling the entire chest, were applied. Half-drop doses of tincture of aconite root, in combination with the solution of acetate of ammonia and sweet spirits of nitre, were given every two hours, alternated by five-grain doses of carbonate of ammonia.

At 9 P. M. her temperature had fallen to 103°; at 11 P. M., but little change; same treatment continued for the night.

20th: At 6 A. M., temperature 103°; pulse 136; respirations 44. Not having slept much during the night, she felt tired and weak. The lower portion of each lung was partially consolidated, and in the upper there were heard exaggerated breathing and numerous crepitant and subcrepitant râles. During the night the eruption had become very much darker, many of the papules looking like dark blotches of extravasated blood. Digitalis was substituted for aconite. Throughout this and the following day she remained in nearly the same condition. At 9 P. M. of the 21st she was given, by mistake, about two ounces of brandy. This caused, for a short time, an increase in the frequency of the pulse and respirations, and gave rise to considerable cough, but the temperature fell about 2.5° within two hours from the time the overdose of brandy had been given.

22d. 8 A. M., temperature 99°; pulse 124; respirations 36. During the day the temperature rose to 102°; pulse to 132; respirations to 40. The pulmonary trouble soon began to lessen, although for nearly two weeks she took, in the way of nourishment, but little beside very small quantities of milk, to which a little brandy had been added. Her improvement, though slow, was continuous, and within eighteen days from the time of the first appearance of pneumonic infiltration only a slight portion of the base of the right lung remained involved, the left lung having almost entirely cleared up.

June 15th. She was looking and feeling well; only a little harshness in the respiratory murmur at the base of the right lung remained. A few days after the pulmonary complication began, the eruption all over the cutaneous surface was dark and hemorrhagic in appearance, presenting during convalescence, before the pigment of the blood was absorbed, the condition seen in so-called black measles. Traces of the eruption were visible nearly four weeks after the beginning of the disease. The urine was repeatedly examined during the attack, but no albumen was detected. So far, no sequelæ have developed.

Remarks —It is a well known fact that physicians in the country (in some parts of the United States, at least) are rarely called to see cases of measles, and that in the majority of instances, in many of the rural districts, when medical advice is sought, it is for some complications or sequelæ, the eruption having disappeared or is fast fading. I remember having seen, when living in the country, large families of children seized almost simultaneously with this eruptive fever, but I never knew a physician to be summoned for any of them.

It is believed by some that the exanthematous group of diseases is less severe in the country than in large cities. For over seven years, during which time I have been actively connected with one, and at times with two, of the largest dispensaries of the city, I had not met with cases of measles presenting very alarming symptoms, until the recent epidemic, which is now nearly over.

I have never lost a patient from the measles or its complications, but Dr. J. M. Keating, in an interesting and scientific paper on "Heart Clot in Measles," presented to the College of Physicians of Philadelphia, the first Wednesday of this month, reported four deaths from this disease, occurring during the spring and winter months of the present year, among the children under his care in the Blockley Hospital.

That some epidemics greatly increase the death rate from measles, may be gathered from extracts from Trousseau, Chadbourne and Raymond, quoted by Dr. V. P. Gibney in his communication on the "Sequelæ of Measles," to the New York *Medical Record* for June 3d, 1882. "Trousseau says, 'In an epidemic which I observed at the Neckar Hospital, in the years 1845 and 1846, out of twenty-four children who had measles, twenty-two died of peri-pneumonic catarrh; the other two escaped this terrible complication. This statistical fact enables you to estimate the frightful severity of this affection . . . . and the physician who considers measles a mild disease till he encounters one of these epidemics will afterward modify that opinion.'

"Dr. Chadbourne, in the *American Journal of Obstetrics and Diseases of Women and Children* for October, 1880, reports an epidemic of measles which prevailed in the New York Foundling Asylum in the spring of that year. There were forty-eight deaths in three hundred cases, twenty children dying of capillary bronchitis, broncho-pneumonia and œdema pulmonum. Twenty died from convulsions."

"Dr. Raymond, of Brooklyn, presented last year a report based upon the returns to the Brooklyn Board of Health, headed 'Measles Not a Trivial Disease.' Even in the limited number of cases of measles reported to the Board of Health of that city, in one year there were fifty-nine deaths from complications. Of lesions pertaining to the nervous system, six died of meningitis and hydrocephalus, thirteen of convulsions, and two of congestion of the brain. Respecting the pulmonary system, three died of congestion of the lungs, one of pulmonary apoplexy, eighteen of pneumonia, and five of laryngitis. Two died of dysentery."

During the recent epidemic of measles, the severity of the disease has been in a direct ratio to the age of the patient. This has been the rule in most cases I have seen, and if the mortality of this exanthema in camp life is due as much to age as to exposure, military statistics would still further substantiate this view. In the late War of the Rebellion, according to Bartholow, one-fifth of all the soldiers who suffered from measles died, their death being due directly or indirectly to this disease.*

Heart Complications.—All authorities are agreed that laryngeal and broncho-pulmonary troubles are the most frequent complications of measles, but endocarditis associated with this disease receives only a passing notice by the most systematic writers on the diseases of the heart. I have hurriedly looked through the works of Flint, Walshe, Da Costa, Latham, Fothergill, Stokes, Hayden, Markham, and Sibson's article on endocarditis, in Reynolds' System of Medicine, but have failed to find a single case of inflammation of the lining membrane of the heart

* Sanitary Memoirs of the War. (Quoted from Flint)

described or referred to in connection with measles. Some of these authors give measles as a cause of endocarditis. Was the heart murmur in Case 1, in this paper, due to endocarditis, or to an altered condition of the blood? The condition of the blood was apparently sufficient to give rise to a murmur, and if the diagnosis of heart trouble had been based upon the abnormal sound heard at the apex of the heart, the subject would scarcely be worthy of consideration. Certain symptoms pointed toward organic heart disease: First, the pulse was very rapid and irritable before the temperature began to rise, and the murmur was preceded, a day or two, by a prolongation of the first sound of the heart; secondly, the murmur was preceded and attended by pain and a sense of oppression over the præcordium, which was relieved by dry cups, sinapisms and poultices; thirdly, the cardiac irritability, as indicated by the pulse, extended well into convalescence.

Laryngeal Complications.—Another point of interest in the recent epidemic of measles was the tendency to diphtheritic inflammation of the larynx. This complication was not well marked in the cases coming under my care, only intense redness of the fauces, attended by great pain in swallowing, being found; but Dr. Keating, in his recent communication to the College of Physicians of this city, reported quite a number of cases of membranous laryngitis complicating measles.

Pulse.—Although many of my cases were doing apparently well, the irritable and frequent pulse invariably manifested at the height of the febrile action made me more or less apprehensive lest something untoward should occur. I have not seen a case of measles during the last four or five months that did not have a pulse frequency, at some stage of the disease, of 120 per minute, and in some cases this was increased to 130 or 140.

Sudden Changes.—The recent epidemic has been marked by sudden and unfavorable changes in the course of the disease. This fact is illustrated by the clinical history of Case 2 of this paper. In this instance a change was unsuspected, for at my morning visit everything, so far as I was able to judge, was doing well, yet in the evening the symptoms, for a time, were so grave that the patient's life was threatened. Several physicians have told me that they have of late met similar cases.

The prevalence, during the last four or five months, of a catarrhal fever, and the altered condition of the blood found in severe cases of measles, were probably the chief causes of these sudden changes.

Prof. DaCosta, on the first Wednesday of last month, presented to the College of Physicians of Philadelphia a concise paper on "Catarrhal Fever," observed during its recent manifestations, briefly detailing the history of a number of cases. In this fever the air passages bore the brunt of the disease, and sudden and alarming symptoms were not uncommon, although death rarely occurred unless the fever was complicated. It is probable that the frequency of typhoid pneumonia, and pneumonia occurring in connection with typhoid fever, during the past winter and spring, may be accounted for by the presence of this semi-epidemic fever. The weather of the present year has favored the development of catarrhal troubles.

To the condition of the blood in measles, until recently, attention had not been directed. The credit of the initial investigations of the blood condition in this eruptive fever is due to Dr. J. M. Keating, of Philadelphia.* He investigated and caused to be investigated the condition of the blood in a number of cases. In the mild cases no perceptible blood alteration was observed; in the cases that were more than usually severe, yet did not present very unfavorable symptoms, the white blood corpuscles, increased in number, contained micrococci in varying numbers; in the severest, and not infrequently the fatal, cases, the white blood corpuscles were increased in number, many of them disorganized, and these blood constituents and the liquor sanguinis swarmed with myriads of micrococci. In all his fatal cases (four in number) death was attributed to heart clot. An objective $\frac{1}{16}$ of an inch was used in these investigations.

If the condition of the blood was, as found in these cases, present in all the worst cases of the recent epidemic, the frequent, irritable and vibratory pulse, and the tendency to heart complication in a number of cases, are easy of explanation.

According to my experience, the recent epidemic of measles, in comparison with its severity, has been remarkably free from cerebral trouble. A few deaths from convulsions and coma have been reported, but the proportion has been small.

Diarrhœa has been present in quite a number of cases, but it has rarely been sufficiently persistent or severe to require special attention.

Treatment.—The common-sense management and general treatment will not be mentioned. In the treatment of some of Dr. Keating's cases, alcohol alone was relied upon for the relief of the alarming symptoms of dyspnœa and flickering pulse, associated with severe pulmonary complication, or with the formation of heart clot. Brandy was given in two-drachm doses, every hour or two, to a child a few years old. This was suggested by Dr. Formad, in consultation, because the latter's cultivated micrococci were readily killed by alcohol.† My cases, when grave pulmonary symptoms showed themselves, were mainly treated, externally, by dry cups, sinapisms, and poultices; and internally, by carbonate of ammonia, digitalis and alcohol. When the body temperature was considerably elevated and the skin dry, small doses of aconite instead of digitalis were given at short intervals. In case numbered two, decided improvement was manifest after two ounces instead of two drachms of brandy were given by mistake. In this case alcohol was not well borne during convalescence, it seeming to increase the evening rise of temperature, while resolution was going on in the lungs.

Remarks upon Dr. Eskridge's Paper.—Dr.

* Read before the College of Physicians.

† In answer to my inquiries, Dr. Formad writes me that "one or two drops of alcohol added to one drachm of his culture liquid stopped the growth and multiplication of the micrococci."

Samuel B. McDowell narrated the following interesting case: Miss —, aged eight years, complained of the ordinary prodromata, and was first seen on the second day of the eruption. The exanthem was well marked, but of a peculiar dark hue. Catarrhal phenomena were not a prominent feature. On the third day the eruption was decidedly purplish and strikingly resembled minute ecchymoses. Patient was in other respects not unusually ill. Was suddenly unable to void her urine, and tenesmus developing, I was summoned. After hot fomentations were applied, urine intimately mingled with blood was passed, and subsequently almost pure blood. The hæmaturia was so pronounced that, upon standing, a large coagulum formed. I neglected to mention that epistaxis preceded the appearance of the rash. No other complications occurred and the rash began to fade on the thirteenth day. Patient is now thoroughly convalescent.

Dr. James B. Walker has observed numerous cases of measles occurring among emigrants' children who were sent to Blockley. The eruption resembled that answering the description of the so-called German measles, and was characterized by efflorescence sharply defined, with interspaces of clear skin. Mild catarrhal symptoms prevailed, accompanied by enlargement of the cervical lymphatic glands. There was no uniformity of the size of individual papules and patches. The back is the region that should be inspected in exanthemata. In measles there are diagonal lines of patches running downward and outward from the spinal column. This I have seen so frequently that I regard it more pathognomonic of morbilli than the reputed crescentic arrangement. In Rötheln this form of the eruption has not been noticed. Regarding sequelæ, one child died of tubercular meningitis immediately after an attack of measles, but whether this had previously existed, or developed as a consequence, cannot be stated, as the parents spoke a foreign language, preventing ascertaining of anterior condition of child's health. Diarrhœa prevailed in all cases in the hospital during recent epidemic, and many fatal cases are attributed to this enervating complication.

Dr. L. Brewer Hall has heard a great deal about eye troubles following measles, but does not know of the truth of the belief. Many eye troubles that result from weakness follow this, as any other asthenic disease, but that they depend directly upon measles, he doubts, or at least is not in possession of reliable data. The debility preceding and following measles aggravates existing eye affections. One case of choroido-retinitis under observation, seems to be due to measles. The evils of a dark, illy ventilated apartment are certainly greater than the advantage, if any, gained by exclusion of light. In phlyctenules and conjunctival affections there is frequently increased congestion of lower quadrant of choroid, and even striation of retina, which, however, are not followed by serious consequences. The ear is frequently the seat of suppuration. The seat of trouble is in the middle ear. Perforation of membrana tympani should be treated promptly, with a view of healing. These troubles are amenable to ordinary treatment.

Dr. J. T. Eskridge noticed that epistaxis preceded the accession of severe symptoms in two cases. Diarrhœa in some of the cases was profuse, but not persistent. Regarding the use of aconite, I consider it very efficacious, even in fevers with considerable prostration, when administered in small and frequently repeated doses. It lowers arterial pressure, promotes perspiration, thereby relieving the harsh, dry skin, and contributes largely to the comfort of the sufferer.

For suppuration of middle ear cleanliness is a *sine qua non.*

The Effects of Certain Remedies on the Irritability of the Cerebrum.

Hitzig studied first the effect of remedies on the irritability of the cortical substance of the cerebrum. P. Albertoni, of Genna, has taken up this subject again and published his observations in the *Archiv. f. Experiment. Pathol. and Therap.* Bd. xv, Heft. 3 and 4, 1882. His experiments were twofold in character. He wished to determine, first, what changes of the irritability of the cortical substance of the cerebrum would take place under the influence of certain remedies, and to clear up at the same time certain questions concerning the treatment of epilepsy.

By experiments it has been clearly proven, that in dogs the electrization of the so-called irritable zone of the cortical substance of the brain produces an epileptic seizure. It is further known that of all forms of epilepsy the most common is that which is caused by a discharge beginning at the cortex of the cerebrum and spreading over the whole nervous system.

Albertoni's experiments were made on dogs and monkeys, with bromide of potassium, atropia and cinchonidia. The results were as follows:—

1. The continued administration of bromide of potassium diminishes in dogs, decidedly, the irritability of the cerebrum. If a brain, under the influence of the bromide, is irritated by an electrical current the effect is *nil* or hardly observable. One single large dose of the bromide will also reduce this irritability in a high degree.

If the administration of the bromide is continued for a long time in dogs, irritation of the irritable zone of the cortex of the cerebrum (especially of the irritable zones for the facialis

and the extremities) with even a far stronger current than that which, in a normal condition, will cause severe epileptic seizures, proves itself ineffectual, causing no response.

The conclusion may be considered correct, that a continued use of the bromide obtunds the irritability of the irritating point of the cortex of the cerebrum, as well as it prevents the spreading of the irritation.

2. Atropia, in not too large, but still poisonous doses, increases the irritability of the cerebrum, as proven by the greater irritability of the irritable zone of the cortex to an electrical current.

The differences in the irritability and in the development of the cerebrum explain satisfactorily the following interesting facts: (*a*) the diminished effect of atropia in children and young dogs; (*b*) the fact that the brain symptoms caused by atropia are far more intense in dogs than in sheep, the brain of which is more developed, but much less irritable; (*c*) the total want of effect of this drug in pigeons, the cerebrum of which is unirritable.

The possibility of inducing epileptic seizures in the larger mammalia by irritating with an electric current certain parts of the cortex of the cerebrum, is, by atropia, neither diminished nor removed.

3. Cinchonidia, in therapeutical doses, increases in epileptics the number of the seizures. As well as all other alkaloids of the Peruvian bark, cinchonidia is contra-indicated in epileptics.

If the cerebrum or the psycho-motoric centres are removed, cinchonidia will still cause epileptic attacks. This drug has an irritating effect on the central motor-ganglia.

The epileptic seizures which take place in dogs when under the influence of large and fatal doses of cinchonidia, are prevented in animals which have been kept for a long time under the continuous influence of bromide of potassium. At the same time, even the largest doses of cincho nidia lose, under such circumstances, their fatal effect. This proves that the bromides are indicated whenever epilepsy is caused by a condition of tension of the nervous centres.

The long continued use of atropia prevents neither the epileptogenic nor the fatal effects of cinchonidia.

In epilepsy due to a condition of tension in the nervous centres, atropia is not only useless but hurtful. It may be administered, however, in fresh cases of epilepsy, caused by fright. In such cases, atropia should be given, up to poisonous doses.

In cases in whom the epilepsy is caused by congestion or obstruction of the blood vessels of the brain, atropia may be of benefit by producing contraction of the vessels, and preventing, in such a way, that hyperæmic state which induced the seizures. In cases of peripheral origin it may also be useful by obtunding the irritability of the peripheral ends of sensory and motor nerves.

———

Treatment of Infantile Gastro-Enteritis.

From observations made in the Children's Hospital at Pesth, Epstein concludes (*Prayer Medic. Wochens.*) that a liquid diet, poor in fatty matters, is the basis of treatment of gastro enteritis in young infants. He recommends particularly an albuminous lemonade, obtained by beating up the white of an egg with a pint of water, previously boiled, the resulting mixture being then carefully filtered. At the Pesth hospital this is prepared fresh three times daily, and is kept in a bottle well corked, and placed on ice. In a word, all precautions are taken to prevent the introduction of micro-organisms into the system.

Nursing from the breast should be completely stopped for the first few days. Every three hours, fifty grams of milk at a lukewarm temperature may be given to the child, either with the bottle or by spoonfuls. The child should not be put back to the breast until the loss of flesh, which is considerable at first, commences to diminish. Again, when at the commencement there is violent vomiting and rejection of yellowish curds, M. Epstein washes out the stomach daily, for from eight to fifteen days, by means of the œsophageal tube. As regards direct remedial measures, M. Epstein employs the following potion:

℞. Sodæ et magnes. benzoat., ℈ iv
Sp. vini gall., ʒ ss
Aquæ, ʒ vj. M.

Sig.—Teaspoonful every two hours.

When there is any tendency to collapse, recourse may be had to the following:—

℞. Tr. valerian, ʒ ss
Vini port (pur.),
Æther. sulph., āā ʒ s°. M.

Sig.—One or more drops of this mixture may be given in a spoonful of water.

When the child presents any sign of cerebral hyperæmia, with great agitation, chloral in small doses may be prescribed:—

℞. Choral. hydrat., grs. viij
Aquæ, ʒ xiij. M.

Sig.—A teaspoonful of this solution may be given every half hour while excitement continues.

Finally, when the inflammation has reached the large intestines, and symptoms of dysentery supervene, it may be attacked directly by the following enemata:—

℞. Ac. boracic., ʒ ss
Aquæ destill., ʒ iij. M.

or with—

℞. Argenti nitrat., gr. xij
Aquæ destill., ʒ ixss. M.

The results obtained from this course of treatment are, it appears, excellent.

———

Sick Headache.

Surgeon Major Roehring, of Amberg, reports, in No. 32 of the *Allg. Med. Centr. Zeit.*, April 22, 1882, a case of headache of long standing, which he cured by salicylate of sodium, which confirms the observation of Dr. Oehlschlager, of Danzig, who first contended that we possessed in salicylic acid one of the most reliable remedies for neuralgia. This cannot astonish us if we remember that the action of salicylic acid is, in more than one respect, and especially in its influ-

ence on the nervous centres, analogous to quinine.

While out with the troops on manœuvre, Dr. Roehring was called to visit the sixteen-year-old son of a poor peasant family, in a neighboring village. The boy, who gave all evidences of living under bad hygienic surroundings, but who had shown himself very diligent at school, had been suffering, from his sixth year, several days every week, from the most intense headache, which had not been relieved by any of the many remedies tried for this purpose. A careful examination did not reveal any organic lesion or any cause for the pain, which seemed to be neuralgic in character, a purely nervous headache. Roehring had just been reading the observations of Oehlschlager, and knowing, from the names of the physicians who had been already attending the poor boy, that all the common remedies for neuralgia had been given a fair trial, thought this a good opportunity to test the virtue of salicylate of sodium. He gave the boy, who, in consequence of the severity of the pain, was not able to leave his bed, ten grains of the remedy every three hours, and was surprised to see the patient the next day in his tent and with smiling face. The boy admitted that he for years had not been feeling so well as he did then. The remedy was continued, but in less frequent doses, for a few days longer; the headache did not return. Several months later Dr. Roehring wrote to the school teacher of the boy, and was informed that the latter had, during all this time, been totally free of his former pain, that he was much brighter than formerly, and evidently enjoying the best of health.

It may be worth while to give the remedy a more extensive trial, and the more so, as we are only too often at a loss what to do in stubborn cases of so-called nervous headache.

The Treatment of Fracture of the Skull with Depression.

On this important and interesting subject the *Lancet* makes the following remarks :—

It is not improbable that in the operative treatment of injuries and diseases of the skull, some of the most important advances in surgery in the immediate future will be made. We now operate freely on deformed bones and diseased joints; operations on the abdominal viscera are now undertaken, which but a few years ago were looked upon as altogether beyond the bounds of the practicable; and the therapeutic advances that have made these procedures so successful may be equally well applied to the surgery of the head. But accuracy in diagnosis is an essential condition of successful treatment, and as the recent discoveries of the special function of individual portions of the surface of the brain are rendering exact diagnosis of superficial brain lesions possible, it is not rash to foretell that surgery will keep pace with the science of diagnosis. The surgical treatment of depressed fracture of the skull has been formulated into the proposition that when accompanied with evidence of compression of the brain, an operation to remove the depressed bone should be undertaken at once. This is the general if not the universal practice among British surgeons. But latterly, some inclination to extend the use of the trephine has shown itself in more than one quarter. The reasons for this extension are that the operation, when properly conducted, and especially when carried out with due precaution against septic infection of the wound, is not a very dangerous one, and if we may argue from Dr. Yeo's experiments on monkeys to man, we may say that the use of the trephine adds very little, if at all, to the gravity of a case. Again, surgeons from time to time see cases where the results of a post-mortem examination show that a life might have been saved by a timely use of the trephine. In Paris the doctrine was first promulgated that the trephine ought to be used in *all* cases of *compound* fracture of the vault of the skull, whether actual depressions of bone, or symptoms of compression, be present or not. And lately in America, it has been urged by Dr. Gunn that in *all* cases of depressed fracture, with or without symptoms of compression, and whether simple or compound, the depressed bone should be elevated. While we fully believe that the operation of trephining has fallen into undeserved disrepute, and might with advantage be resorted to more freely, we think that Dr. Gunn's proposal is unsound and dangerous. It is a familiar fact to any surgeon of large experience that patients who have received depressed fractures go through life quite unaffected by them, and while such is the case no appeal to cases in which the cour e of events is different ought to induce a surgeon to submit all cases alike to operation. For there is not conclusive evidence before us that the evil effects of depressed fractures, which often arise, may, without giving rise to symptoms, advance to such a degree as to render trephining useless. There appears, then, to be no sufficient ground for formulating the rule of practice otherwise than as at present, but it should be more liberally interpreted, close watch for symptoms of local mischief should be kept up, and the trephine resorted to as soon as any such symptoms declared themselves, even though slight, and with strong hopes of a successful issue, instead of, as at present, looking upon it as a *dernier ressort*, and using it timidly and with gloomy foreboding.

A Peculiar Idiosyncracy as to Mercury.

In the *Practitioner* Dr. Simeon Snell reports the following unusual case :—

Mrs. C., a widow, aged 41, by occupation a monthly nurse, was sent to me on October 26th, 1881, by her medical man. For some weeks she had perceived that her sight was getting defective, but especially the right eye had become worse quite recently. She had suffered from slight rheumatism at different times, and now attributes her complaint to "cold," but there seems good reason to suspect a specific taint.

In both eyes the vitreous humor was hazy, and floating films were noticed, especially in the right eye. The left pupil dilated well to atropine, but the right displayed a tag of adhesion at its lower part. R. V. $= \frac{20}{70}$; L. V. $= \frac{20}{50}$. The patient was hypermetropic ($\frac{1}{36}$), and the vision of the left eye was materially improved with the

appropriate glass. Iodide of potassium in 4 gr. doses, with cascarilla, was prescribed; and atropine drops were ordered to be instilled into the eyes.

October 29th.—She is to-day somewhat better.

November 8th.—In the right eye a more acute phase of iritis is noticed, and in the left the films in vitreous are more marked. A drachm of the liquor hydrarg. perchlor. was now added to each dose of the mixture.

In the course of the next few days I heard from her medical man that she was much worse; "he was at a loss to account for her symptoms;" and on the 12th he had stopped the mercurial He desired me now to admit her into the Infirmary. The patient has since told me that she commenced the fresh medicine (hydrarg.) on the 9th, and that after three doses of it she felt ill, and continued to get worse while she was taking it.

On November 18th she came to the Infirmary, but appeared so weak, and told me also "that the vomiting which commenced while taking the medicine" had only ceased for a few days, that it seemed desirable to place her on the medical side of the house, and she thus passed under the care of my colleague, Dr. Bartolomé. Under his treatment her general health rapidly improved. On December 20th, however, the perchloride was again ordered. The next day the temperature had risen to close upon 104°. There was vomiting, also, not merely after food or drink, but at other times; the tongue was furred, and complaint was made of pain in the head. On the discontinuance of the mercury and the substitution of a stomachic, the temperature fell, with a corresponding improvement in her general condition. Subsequent thermometric observations displayed a normal temperature, with occasionally a very little above.

As I have intimated, she recovered again, and on January 12th, 1882, was transferred to my care in much improved health. The pupils dilated well under atropine, but the edges were somewhat irregular, and the vitreous in both eyes was turbid. In addition to continuing the atropine, on January 15th a mixture of citrate of iron and quinine was prescribed, and a powder of 2 grains of hyd. c. creta was ordered to be taken twice daily. She probably had one of these powders the same evening, and there was a rise of temperature, with the vomiting and general disturbance as before. I believe she only had three, or at the most four powders. The fall of temperature after their discontinuance was marked; there was a subsequent rise, caused, I fancy, by a troublesome alveolar abscess.

Under small doses of potassium iodide she has since done well.

The foregoing case is of interest as exhibiting an unusual effect of mercury. It is not uncommon to meet with cases in which a small dose of the drug has produced salivation, but in the case under consideration there were no signs of ptyalism. Twice, however, it is seen that a rise in temperature occurred after the administration of the mercurial. No record is at hand of the temperature in the illness, after the use of the perchloride of mercury and iodide of potassium before admission to the infirmary. I apprehend, however, that there can be little doubt that it was similarly affected as in those instances more closely observed.

It should be added that the urine was normal.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

—"The Genius of Medicine," is the title of a very interesting address, delivered before the Florida State Medical Association by Dr. Robert B. S. Hargis, of Pensacola, Fla. It is really a short and very concise account or history of the progress of the science of medicine from the earliest days to the present time. While it does not take the place of more pretentious volumes on this interesting subject, it yet will serve to impress on the mind of the reader the dates of, and circumstances attending, the advent of the most important events in medical history. A short account is given of the introduction and progress of sanitation in our country. The author tells us that in the earlier part of the decade from 1860-70 the chief sanitary officer of the city of New York was a very ignorant politician, and its sanitary inspectors were keepers of grog-shops. One of them, when asked, "What is hygiene?" answered, "*a mist arising from the ground;*" while another stated that the best preventive of smallpox was to "burn coffee in the room." The author pays a high tribute to Dr. Stephen Smith, of New York, to whose unremitting exertions we owe the existence of the American Public Health Association. The essay comes to us in the form of a reprint from the July number of the New Orleans *Medical and Surgical Journal*, and we regret to say that numerous typographical errors and misplaced punctuation make it rather difficult to read.

——Dr. John MacKenzie, of Baltimore, has had his attention called to the frequent existence of ulceration of the trachea and bronchi in patients suffering from pulmonary phthisis. Desiring to determine whether there existed any relation of cause and effect between these two conditions, the opportunity was afforded him of making examinations of the respiratory organs of all patients dying of phthisis in the Rudolph and Jewish Hospitals of Vienna during a period of five months, and the result of these valuable observations he has incorporated into an address delivered before the Medical and Chirurgical Faculty of the State of Maryland, a reprint from the transactions of which we have received.

The author noted that these ulcerations, for the most part superficial, irregularly round or oval erosions of the mucous membrane, varying in size from a pin's head to a small pea, and tending to coalesce and form large ulcers, were most frequent in the lower portion of the trachea and bronchi. He has seen the trachea in its entire length and circumference, together with the bronchi on both sides, almost completely destroyed, and its mucous membrane converted into a gangrenous mass. These ulcers are never found in the bronchi of the unaffected lung. The Doctor concludes that his observations go to show that diphtheritic ulceration of the larynx, trachea and bronchi occurring in the course of pulmonary phthisis is related to the affection in the lung in so far as it is produced by the corrosive action of the sputa; but that in the present state of our knowledge it is impossible to affirm its specific tubercular nature.

——By degrees we are adding one disease after another to what might be termed the "Bacterian Class." Bacteria, bacilli, micrococci, etc., are terms heard on every side, and yet few, comparatively speaking, have any true conception of what the terms mean. Dr. Charles S. Dolley, of Rochester, New York, in a paper read before the Rochester Society of Natural Sciences, has furnished a very lucid and interesting account of the main points connected with bacteria. The term bacteria, while used comprehensively to designate the whole class of minute organisms under consideration, the author considers an error, since the *bacteria*, in truth, constitute one distinct species, viz: the short, rod-like organisms; then we have the round or oval, which are *sphero-bacteria* or *micrococci*.

Bacilli are those long, stiff, fibre-like bodies, while similar organisms, *yet flexible*, are known as *spirochæte*. Similar long bodies, when curled liked a corkscrew, are called *spirilla*, and when merely wavy or curl like, *vibrios*. Bacteria are very small, a cube the size of a pin's head would contain six hundred and thirty-three millions, and they increase with such rapidity that the progeny of one single germ would, in less than five days, fill all the seas of the world, as stated by Cohn. These bacteria are considered to be the means of conveying disease, in certain instances, because of the morbid material which they contain at the time, but are not in themselves the cause of disease. The greater proportion of bacteria are transparent and colorless. Speaking of Pasteur's researches into the bacteria of disease, Prof. Huxley has said that they fully balance the ransom of $1,000,000,000 paid by France to Germany after the war of 1870–71. This pamphlet is well worth the perusal of all those who have but a vague and indistinct notion of the nature of bacteria.

BOOK NOTICES.

Transactions of the Indiana State Medical Society, 1882. Indianapolis: 1882.

These Transactions make a neat and well printed volume, and the contents are worthy of preservation in book form. Besides the usual proceedings, necrology, etc., there are a number of original articles. The address of the President is an excellent summary of the advantages of sanitary legislation. Of the other papers we may mention one of interest on the health resorts west of the 100th meridian, by Dr. E. S. Elder; a discussion of the treatment of that formidable disease, epidemic cerebro-spinal meningitis, by Dr. R. F. Stone. His treatment is decidedly active and positive, and we should like to have had statistics as to its results. The management of still-born children after resuscitation is a very judicious paper, with many useful directions, by Dr. Wm. H. Bell. Other papers are published from Drs. A. G. Preston, J. R. Weist, Thad. M. Stevens, Mary M. Thomas, N. Field, H. V. Sweringen, J. W. Compton, etc.

The volume may be obtained of the Secretary, Dr. E. S. Elder, Indianapolis.

Atlas of Gynecology and Obstetrics. Edited by Dr. A. Martin. Folio. Published by A. S. Wilde & Co. Cincinnati.

This large and handsome publication is well worthy the attention of the general physician and those who pay special care to the diseases of women. It contains four hundred and seventy-five black and thirty-seven colored illustrations, selected from the works of a large number of eminent European writers. It also has a supplement embracing a number from the "Nouvelles Demonstrations d'Accouchements" of Prof. J. P. Maygrier.

An examination of a number of these plates show that they are accurately drawn and colored, and they cannot fail to be of great use, especially to those whose opportunities of refreshing their anatomical knowledge by dissection are limited.

The work is published only by subscription, and those desiring to purchase should address the publisher directly, who will forward full descriptive circulars.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

TARDY WISDOM.

The cable telegraph, one day a week or so ago, sent the following item of news flying over the western world:—

A CRITICISM.

LONDON, Aug. 11th.—The *Athenæum* says Prof. Esmarch, the eminent German surgeon, has published a lecture which he delivered before the Physiological Society at Kiel, on the treatment of General Garfield's wound. Prof. Esmarch's lecture was to the effect that General Garfield might have been alive but for the treatment he received.

We will suppose the above item is true. It probably is nearly so, as the *Athenæum* is a careful and well informed paper. We ask, is it possible for Prof. ESMARCH or anybody else to form a correct opinion about a confessedly ob cure and intricate case without seeing it? Is it fair to pronounce criticisms adverse to the skill of surgeons, when these criticisms are based upon facts developed after the case had terminated, and which could not have been known before?

We have heard of a man who remarked to his censors that there are many cases where it is the most difficult of all things to exercise a judicious foresight; but that anybody can rely upon their *hindsight*. So we think that Prof. ESMARCH, or any other surgeon, with a full knowledge of the lesion in the late President's case, might suggest something which might have been done that was left undone; might object with reason to something done, which had better been left undone. But is not this the history of every unfortunate case? And is there any guarantee that if these steps had been taken the result would have been different? None whatever.

Consultations "by letter" are well known to be unsatisfactory. Some most acute diagnosticians decline to pronounce an opinion on any case where they do not have an opportunity to see the patient. Yet surgeons had, and still have, no hesitation about advising and criticizing this case of gunshot wound. Yet not one of them would be willing to treat a case by hearsay. This indicates a contradiction between their literary and their practical life which should not exist.

Guiteau said that the doctors had killed the President. But he could not find among the many who had shown themselves willing enough to intimate as much in newspapers, medical journals and private conversation, any one of standing who dared come forward and back his opinion on the witness stand. Either they were cowardly enough to let a man be hanged for an act he did not commit, or they had been saying what they knew they could not sustain under cross examination.

Such expressions were unfair, because they had not sufficient grounds to rest upon. Every one, no matter how eminent, is open to candid criticism. But to claim that the result would have been different had the treatment been other than it was, or to blame the attending surgeons for ignorance of what they could not have known during life, is unjust.

POLICE SURGEONS.

Two recent occurrences, one in England, the other in our own charitable city, call loudly and in unmistakable terms for a well organized and well paid corps of police surgeons. In our city, a man was recently found lying on the street in

an unconscious condition; naturally supposing him to be drunk, for he knew nothing of medicine, and his very calling causes him to regard every one found under similar conditions as intoxicated, the police officer arrested this man and took him to the station-house. The lieutenant in charge, having no more knowledge of the various morbid and dangerous conditions that may nearly simulate alcoholic intoxication, confined this unfortunate to a cell. Shortly afterward he was found dead. Upon subsequent investigation, it was ascertained that this man was a person of respectability, of temperate and industrious habits. While walking on the street on a very hot day he had been overcome by the heat, and had perished from sunstroke when possibly intelligent professional treatment might have saved his life. A case very similar to this one has been reported as having recently occurred in London. We had occasion some time ago to note the case of a young girl in England, who, being among strangers, was supposed by all who saw her to be drunk, when in truth she was dying from acetonæmia, and did perish within a few hours. It is unnecessary to insult the intelligence of our readers by detailing the various conditions, such as uræmia, acetonæmia, narcotic poisoning, and the like, that are very apt to be mistaken for the stupor of alcohol by one not accustomed to meet with these conditions. Besides, we must bear in mind that alcoholism, alcoholic coma, is in itself a dangerous condition, capable in certain cases of extinguishing the spark of life, and therefore a condition that requires active medical interference. The profession is in a measure prepared to recognize dipsomania as a material disease, and all are agreed as to the dangerously poisonous effects of large doses of alcohol. Therefore, it is not always safe to leave a man in a drunken stupor to "*sleep it off*" and "*come to of himself.*" To remedy this void in our civilization and philanthropy it will be necessary for our city fathers to make an appropriation for and to organize an efficient corps of police surgeons, whose duty it shall be, each in his respective district, to respond as promptly as possible to all calls made upon him from the station-house to which he has been assigned. Further, it should be made the imperative duty of each police lieutenant to immediately summon the district physician to every prisoner who may be brought into the station-house in an unconscious condition, as well as to all who may complain of being unwell. The cost to the city would be comparatively small (even though thoroughly competent physicians were procured by the payment of liberal annual salaries) when viewed alongside of the enormous wastes and steals of the public money. From a humanitarian standpoint, it would be better to have the physician summoned unnecessarily a hundred, yes a thousand times, than that one worthy citizen should perish like a dog, as in the case just quoted.

Notes and Comments.

A New Way to Detect Stone in the Bladder.

Dr. James McKenzie Davidson, in the *Lancet*, calls attention to the "auditory method" of detecting vesical calculi. This simple method consists in connecting the end of the catheter with the ear of the surgeon by means of an india rubber tube. A light rubber tube two feet long and with a bore three-eighths of an inch in diameter was employed. One end was slipped over the handle of the sound and the other end held close to the ear. No difficulty was experienced in exploring the bladder, because the tube was so flexible, and it only required a little care to prevent the interference of extraneous noises, as rubbing against the coat, etc. A small calculus was introduced into the bladder (for experiment) and when nothing could be heard or felt by the sound alone, yet by means of the tube the calculus was distinctly and unmistakably heard. With a large stone the click was greatly intensified when heard through the tube. A small piece of coal was crushed to rough powder and introduced into the bladder. The ordinary method revealed nothing, but through the tube a rough, grating sound was distinctly heard.

This method of exploration of the bladder may yield important practical results. Not only may (1) a small calculus be detected which would be otherwise overlooked, but (2) it may be that practice will enable the operator to distinguish the size and character of the surface of a calculus readily; and (3) it also appears likely that a

somewhat similar ear connection with a lithotrite will enable the operator to find and secure small fragments more readily, and so crush them.

Compound Fracture of Both Arms.

Mr. E. Downes reports, in the *Lancet*, the following case which occurred in the Kashmir Mission Hospital: A boy, about fourteen years old, met with an accident by which both bones of both arms had been broken one and a half or two inches above the wrist. After receiving the injury he walked twenty miles and received no treatment for ten days. Upon entering the hospital the wounds on both arms were dirty and stinking. There were two wounds, one for each bone, and the right hand was swollen, and pus could be pressed up into the wound from the palm. The large blood vessels appeared uninjured. After the wounds had been cleansed the ends of the bones were sawn off and the limbs were put in bracketed splints, dressing the wounds with lint and carbolic oil. For two weeks the boy lived in great agony, opiates failing utterly to relieve his suffering. Finally improvement came; the discharge became more healthy, the hands looked more natural, pain diminished and appetite improved. After six weeks union was noted. From time to time it became necessary to slit up sinuses into which pus had burrowed. He was discharged after two months and a half; at this time the fingers of the right hand were not of much use and the left hand was somewhat stiff; he could, however, flex the hand and fingers; he could even hold a stick with his left hand, though the grasp was not firm. This case serves to show what can be accomplished by conservative surgery.

The Long Continued Use of Lime Water with Milk

At a recent meeting of the Medical Society of the County of Albany (*Med. Annals*), Dr. X. T. Bates presented a paper on this subject, in which he suggested that the long continued use of lime water and milk may result in the formation of a cement of casein and lime, which will prove a mechanical obstacle to the function of the bowel. Two cases were reported, both of typhoid fever, where milk and lime water was used. In both cases the patients (when convalescent) were taken with severe pain in the abdomen; the first case died unrelieved after ten days. In the second case the rectum was found filled with dry, stony-hard fæces, when broken presenting a gray, glistening appearance resembling cement. These were removed mechanically every day, the paroxysms recurring for eight days, when they ceased and the patient recovered. The discussion was unfavorable to Dr. Bates' theory, which was considered untenable. There is so little lime in lime water that the quantity taken to produce mechanical troubles by its presence would have to be enormous. Milk, alone, will prove very constipating to some persons, and will produce just such hard, glistening, grayish fecal masses as described by Dr. Bates, and they will have to be removed mechanically, causing the patient the most excruciating pain.

Sciatica Cured by Nerve Stretching.

Dr. Truman reports in the *Lancet* the case of a woman whose occupation had required her to sit for many hours daily on a hard wooden stool. In the summer of 1879 she commenced to feel pain down the right leg, which continued, though not very severe, until July, 1880, when it became intense, and since that time she has suffered daily. For two years every known internal remedy and external application has been used in various hospitals, with hardly any relief. On October 21st, 1881, an incision was made at right angles to the course of the great sciatic nerve, through the skin and superficial fascia, the lower edge of the gluteus maximus found and followed to the tuber ischii. The finger was passed deeply down by the outer side of the long head of the biceps, and the nerve identified and drawn to the surface. Two or three steady and vigorous pulls were given in both an upward and downward direction (toward the pelvis and foot, respectively.) The nerve was then allowed to sink. There was no hemorrhage requiring a ligature. A horse-hair drain was placed in the wound, the edges of which were brought together with silver wire sutures and the whole dressed antiseptically. For several days she had very high temperature, which was successfully combated with quinine.

November 16th she was discharged, and up to the present time has had no pain whatever.

Pilocarpia in Diphtheria.

Drs. Archambault and Pousson (*L'Un. Méd.* No. 20–25, 1882) have made a number of observations with the citrate of pilocarpia in diphtheria. They had opportunity of noting its effect in seventeen cases, and have come to the conclusion that instead of doing any good, pilocarpia is undoubtedly *harmful* in diphtheria. None of the cases improved under it, nine died. Seven cases died after the first hypodermic in-

jection. The more the child seemed susceptible to the action of the pilocarpia the more rapidly the case became worse. This confirms the view of other observers.

Willow Leaves in Ague.

The *Lancet* says that an Indian surgeon, Chetan Shah by name, has recently revived the use of willow leaves in intermittent fever. This is an old remedy, now almost forgotten in Europe, while the leaves of several species of willow are still largely prescribed by hakims of India and Afghanistan, especially in the form of a distillate. Among the lower classes of Cabul, and especially in women, quinine was found to irritate the bowels, while the juice of the fresh willow leaves, largely diluted with water, rarely failed to cure intermittent fever, and never caused irritation. In pregnant women the willow leaf is almost always found preferable to quinine.

Glycosuria in Cases of Poisoning by Carbonic Oxide.

In two cases of severe and almost fatal poisoning by carbonic oxide, Dr. O. Kahler (*Prager Med. Wochenschr.*, 1882, No. 48–49,) detected in the urine which was passed during the first twenty-four hours after the poisoning a decided quantity of sugar. In the one case, a servant girl, thirty years old, 0.9 per cent. was found in 1200 ctm. urine, and a still larger quantity was detected in the second case. After cessation of the sugar in the first case, traces of albumen were found in the urine.

The cause of this presence of sugar is believed to be the action of the carbonic oxide on the prolonged spinal cord, similar to the puncture of the floor of the fourth ventricle; but Kahler supposes that the disturbance in respiration may produce it. The fact is undoubtedly of some value for diagnostic purposes.

Special Reports.

NO. XI.—SURGICAL INSTRUMENTS.

The theory of the production and treatment of fractures of the patella are subjects upon which, of late years, every surgeon seems to have felt it incumbent upon himself to particularly study, discuss, and suggest new reasons and new modes of procedure for relief, hence proving two things; first, the great importance of the subject; secondly, the fact that we have not definitely settled and determined without exception the proper course to be pursued in dealing with this bone of contention. It is evident that the primary indication to be met is the holding of the fragments in such position as to get the closest possible union of the fragments, but how to accomplish this desirable result with the least possible chance of failure or the production of worse mischief has been the mooted question. As to how fracture of the patella is produced, it seems to be the common supposition that when a person falls, striking directly or obliquely upon the knees, a fracture occurring under such circumstances is the direct result of the violence of impaction. Theoretically, this seems very logical, but if we pause for a moment to study the mechanics involved, the point at which fracture of this bone usually takes place, and the nature of the fracture, we are constrained to considerably modify our views. The commonest location of the seat of fracture of the patella is in a transverse line across the bone, in the immediate neighborhood of the tendon of insertion of the quadriceps extensor femoris. There are two other forms of patella fracture, however, which are much rarer than the one first mentioned, these being, in the order of frequency, the comminuted fracture, in which the bone is splintered into more than two pieces, and the vertical form of fracture, in which the separation is in the direction of the long axis of the bone, two vertical halves being created; these latter two are generally of more serious import than the transverse, from the fact that to produce them requires that a very great degree of violence is necessary, which violence generally does not exhaust itself upon the patella only, but upon the knee-joint also, laying it open, and thus greatly complicating the case. As a rule, fracture of the patella is the result of a sudden tension or spasmodic contraction of that great tendon of the leg which inserts upon the upper half of this bone, its lower half giving attachment to the tendon (commonly regarded as a continuation of the quadriceps) which runs down to be inserted upon the tibia. Now from the location of the patella it is in a very favorable position for the easy production of a fracture in the case of a violent fall, the condyles of the femur affording a fulcrum over which tremendous leverage may be exercised.

In falling forward, especially where one trips unexpectedly, there are generally made a number of violent efforts to regain an equipoise; in this attempt the muscles on the front of the thigh play an important part; the instinct of the individual makes him make violent effort to extend the leg, the body being unconsciously suddenly retroflexed; thus a decided contractile effort is made by the extensor quadriceps, there being a

direct ratio between the contractile efforts of the muscle and the attempt made by the individual to save himself; thus the upper part of the patella is violently dragged upward; in the meantime, the flexors of the leg have, in falling, a balance of power which did not before belong to them, they are acting to the very best possible advantage; this being so, their force is propagated along the tibial attachment of the tendo-patellæ, tending to drag down the lower half of that bone, while posteriorly the bony structures back of the patella not permitting the bone to be forced backward, as it normally would be, as the resultant of these two forces, acts as the fulcrum over which it is broken, so that it is probable that in cases of fracture of the patella, the damage is done before the bone has come in contact with the ground; when a person falls backward, the same mechanical principles will apply; the body being thrown violently back, extreme extension is made upon the quadriceps; the fulcrum is the same; the patient, in his efforts to recover himself, unconsciously, almost, flexes the leg on the thigh, uses the ball of the foot and the toes as a steadying point or fulcrum, and will generally, before he falls, make a violent effort of flexion of the leg, accompanied by a spasmodic forward and downward thrust of the femur; thus we have two fulcrums acting, the metatarsal phalangeal articulations below, and the articular expansion of the femur above, at the point at which the patella is situated; the powers are represented by the quadriceps extensor and by the muscles of flexion; the resistance to be overcome is simply the cohesive and adhesive forces in the particles of the patella. If any one will himself go carefully through the experiment of falling forward and backward, he will, I think, find that what is here set forth actually takes place; that there is violent extension, plus a counter effort of flexion, and in falling backward, at the end of the fall are abduction and rotation outward of the foot and lower part of the leg, thus giving a twisting, screwing motion to the tendon between the patella and the tibia.

Of course, these remarks will not apply in those cases where fracture is the result of direct violence, as in the case of a direct blow which splinters or comminutes the bone, or a knife thrust, which divides it into two lateral fragments. Experiment has shown, however, that the patella will stand an extraordinary amount of direct violence without fracturing, this, no doubt, being partly due to the slipping motion which this bone has when struck, thus enabling it to glance out of harm's way. We think we may say there is a universal belief in the fact that muscular violence is the principal factor in the production of this lesion when fracture is the result of a fall. The existence of fracture having been once established, the first question to arise is that of treatment, and this has been the stumbling block of the profession. The great trouble has been, it seems to us, that in many cases too much has been attempted too soon. This has been especially the case when hooks of various kinds have been employed in the treatment of this fracture; in no place is the beauty of the advice, "learn to wait," better exemplified than here. Under no circumstances is it advisable to employ hooks until the entire subsidence of the first inflammatory action, and the disappearance of the swelling which takes place immediately after the receipt of the injury. If hooks are introduced during this period the most lamentable results may be precipitated, not the least of which is erysipelas. The law is that the hooks should not be introduced before a week or ten days have elapsed from the time of injury, and not even then if any irritation whatever remains at the seat of injury. The Malgaigne hook has been for a number of years employed by many surgeons in the treatment of this fracture, and while some have praised others have reviled it.

With the construction of the Malgaigne hooks every surgeon is familiar, the apparatus consisting, as it does, of four hooks, in pairs, each pair being arranged on a sliding frame. While they answer the purpose of holding the fragments of a fractured patella together, they present the disadvantage, which is at times very great, of being applicable only in certain limited positions; while one hook or the hooks on one side may be readily and properly fastened, the others must take their chances of securing a proper position. Further, they are made to work together on immovable straight lines, while, primarily, the fact exists, that the bone over which they are placed not only presents no straight surfaces, but is decidedly asymmetrical; the result is that it is not always possible to hold properly in position, by Malgaigne's hooks, the fragments of a fractured patella after they are brought into position. Taking all the above facts into consideration, it is evident that more or less modification of the hooks was very desirable, for while in many respects the principle upon which they were founded was admirable, yet in construction they lacked some of the needful qualifications to adapt them to the work they were intended to do. A number of gentlemen in the profession have made more

or less modifications of the hooks, the most recent having been made by Dr. R. J. Levis, of this city. Levis' modification consists, first, in separating the hooks into two pairs, each of which pairs is again separated, in a manner which we shall describe later. Further, the *ends* of the hooks in this improvement are made decidedly longer, more delicate, and *sharper* (more pointed) than in the original apparatus, this improvement permitting of more easy introduction, as well as affording a deeper and consequently better hold upon whatever structures they may happen to come in contact with ; there is, besides, less irritation produced by the presence of these long, comparatively finely-pointed hooks, than by the shorter and more blunt hooks of the original. We shall consider one pair of hooks only, the instrument being symmetrical on the two sides. A flat bar of steel, two inches in length and half an inch in the transverse diameter, from which a section is cut extending from the stationary screw socket or head to the end of the bar, thus leaving two lateral tongues upon which the movable hook of the apparatus travels ; this arrangement is shown in figure *D*. The permanent

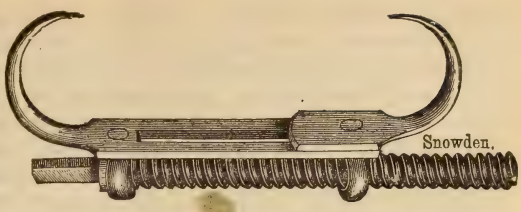

FIG. D.

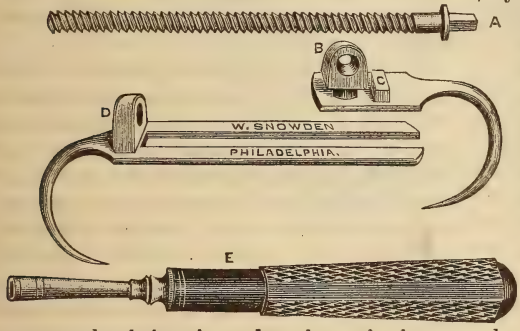


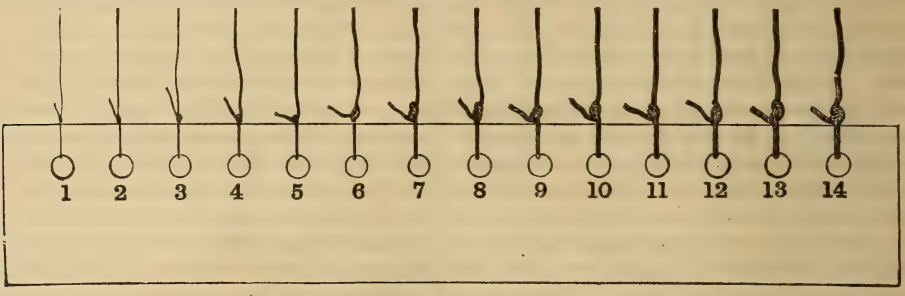
screw socket being situated as shown in the cut, just where the hook begins to spring from the body of the instrument, a screw, *A*, which can be tightened or loosened at pleasure by a key, *E*, plays through this screw bed as well as through the eye, *B*. The nut or elevation, *C*, fits into the tongued portion of the apparatus and prevents all wabbling ; while *B*, acting on a pivot, permits the points to be introduced at any distance apart before it is turned into its transverse position and securely fixed by being held by the screw, *A*.

In the accompanying figure the appearance of the apparatus is shown when fixed in position. The result of the arrangement of the hooks in pairs is that they accommodate themselves to any position of the fragments, the movable part being introduced last. Again, by thus dividing Malgaigne's hooks into two lateral halves, the pairs may be separately removed and replaced as desired, which is, of course, a desideratum. There has been, we admit, a great deal of objection in many quarters to the employment of hooks of any description in the treatment of patella fractures ; but we must pause and ask if many of the failures and unfortunate contretemps reported have not been largely due to the inexperience or haste of those employing them ; in this, as in everything else, there is a law which must be rigidly and unvaryingly adhered to, and this law is altogether in regard to the time of application of the hooks ; we repeat, that under no circumstances should the hooks be placed in position before any effusion that has taken place has disappeared, and all swelling subsided, the cases in the meantime being treated as fractures and injuries in other parts of the body and under the same circumstances usually are, any undue overaction or symptoms being combated. Dr. Levis claims that since the employment of these hooks he has seen a number of cases recover, with osseous union, or with such a close coaptation of the fragments as to be indistinguishable from such a desirable result.

PANCOAST'S IRON-DYED SILK SUTURE.

The subject of sutures has of late years been very largely discussed, and many modifications and additions made in this branch of the surgeon's armamentarium, till the list now embraces very nearly everything that possibly could serve the purpose of a suture, from gold wire down through lead, iron, silk and catgut, and all their modifications. The objection we have found to the employment of metal sutures has been that they are more painful in removal than those sutures made of softer material, that certain ones of them, when employed in the exposed portions of the body, have at times a tendency to leave their stains in the tissues in which they are imbedded, and that they cannot be readily accommodated to the size of the eye of the needle with which one may be compelled to work. True, the file will readily remedy this defect, but one does not always have such an instrument handy, and if he does, he does not

care to be bothered filing wire. To meet some of the indications above pointed out, Dr. Wm. H. Pancoast has recently had made an iron-dyed silk, the silk being pure and guaranteed not to contain a cotton filling, as certain silks are known to have. These silks are made in sizes ranging from a very fine thread, suitable for use in operations around the eyelids, etc., to those heavy enough to be employed in ligating the large arterial trunks. Being iron dyed they are not likely to set up any irritation in the tissues, as those silks are which have been colored by chemical processes; the color is warranted to be fully fixed and not to run under any circumstances. Dr. Pancoast claims to have had much more satisfactory results since using this material than when other agents have been employed, and that less irritation is set up by the silk than any form of wire or other suture. As he has been experimenting in this matter for the past three years, his conclusions are worthy of consideration. Personally we have not had, as yet, sufficient experience with the silk to express an opinion, but from accounts given by those who have used it, we are inclined to regard the agent favorably. The plate shows the size of the threads and their commercial number, by which they can be ordered.



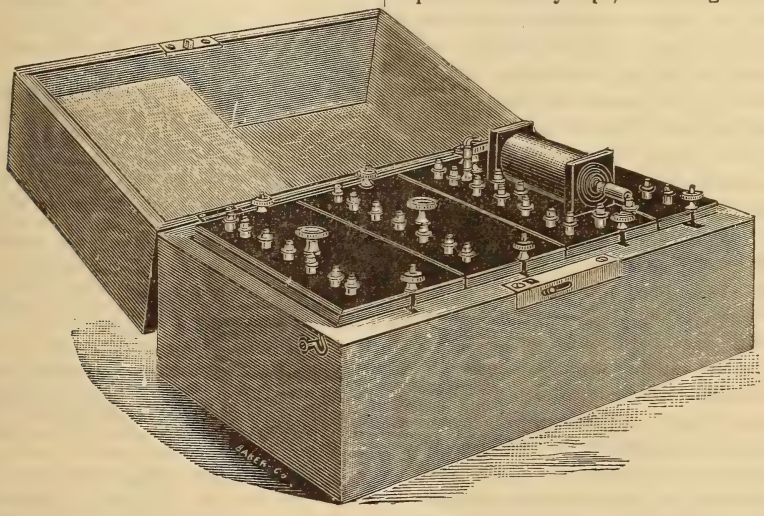
A NEW UTERINE SOUND.

Ease in arriving at a diagnosis is to-day one of the great desiderata of the gynæcologist, and we must admit that, for his assistance, his instruments are, in a measure, as yet almost primitive in their simplicity. These remarks apply more especially to the instruments employed in the diagnosing of flexions and versions in their different degrees. We need some apparatus that, while it is following its course inter-utero, will show, extra-utero, to the manipulator just what course it is pursuing, and the degree to which flexion or version has taken place. Now the expert gynæcologist, of course, will claim he stands in need of no such instrument; that his uterine probe or sound is all that he needs; that he can bend it to a certain curve, introduce it, and that he will almost infallibly be able to tell just where it is, and about what course it is describing: but he must remember that there be those who are not experts; that there are young graduates who have no more knowledge of how to introduce a uterine sound than they have of Choctaw, the average student's experience, under the comprehensive plan of instruction in our so-called first-class colleges, being that which he has had by seeing his professor dexterously give the sound a certain curve, or perhaps only lining the curve out in a general way, on a blackboard.

We are free to confess that we consider it a decidedly risky business to intrust half the graduates with a uterine sound immediately upon their entrance into the profession, and it is for these men, and others too, at times, that an instrument somewhat of the nature under discussion is needed. A sound has made its appearance in this market, introduced, we are told, by a Boston house, that in some respects, when improved, we think will prove a very valuable instrument. It consists of a wire spring or shaft, of about the diameter of the uterine sound, made after the manner of the dental engine flexible shaft; this metal spring, for that is about what it amounts to, measures 12 or 14 inches in length, and possesses a very great deal of flexibility; a thin layer of soft rubber protects the metal portion from all fluids, and hence prevents rusting, etc. A wooden handle is placed about nine inches from the distal extremity. The theory of its operation is this, that the near or external end of the instrument bends in a direct ratio to that of the distal end and in an opposite direction; in other words, if the distal end describes retroflexion, the external extremity will be bent into an anteflexion, the curve expressed being directly as the curve of the concealed end, only in the opposite direction. As we have before said, we have not been enabled to test the instrument ourselves, as yet, but it seems that it might be of use, not only in

uterine examinations, but in examining many other portions of the economy.

Our objections to the instrument as at present made are, that primarily it is roughly finished, the work, seemingly, having been carelessly and hurriedly done; we would suggest as an improvement, that the tips of the instrument be probe pointed and rounded off, instead of being left as they now are, square and more or less sharp on the edges; further, if the last inch were made a little bit more flexible, it seems to us that it would be an improvement, as the instrument would then respond much more quickly to every obstruction or bend met in its course; the rubber coating might also be considerably improved; taking it for all in all, we may say that the idea is fairly good, but the workmanship deficient.



Another instrument recently introduced into this country, from Paris, is the graded nest of hard-rubber anal bougies. Of these there are half a dozen assorted sizes, varying from one and a half inches in diameter down to about a quarter of an inch in diameter; the instruments are made of hard rubber, highly polished, are about twelve to fourteen inches in length, and are packed one within another, thus providing for ease in transportation and doing away with the necessity of carrying a box.

Messrs. Kern, who have imported this instrument here, show also a French syringe for irrigating the eye or ear; this consists of a somewhat flattened barrel, holding about one ounce of fluid, to the extremity of which a cap is screwed, the end of which cap is perforated by pin-holes, to give egress to the water, etc., used; in case it is desired to change the stream from a divided to a solid column or discharge of fluid, all that is necessary to do is to fit over the irrigator a tubular cap, which forms part of the instrument. The chief objection to the syringe is its small size, but it is probable that they will shortly be made to hold larger quantities than they now do.

In the way of electric batteries the latest claimant for popular favor is the McIntosh. A great many are in search of a battery that will give both a galvanic and faradic current. This battery consists of a walnut box, in which is contained a hard-rubber compartment divided into six subcompartments and a drip box; the battery plates consist of zinc and carbon clamped to a hard-rubber top or lid, by means of thumb screws, this rubber plate acting as a cover for the drip cup or the battery cups, according as the battery is active or quiescent; six sets of plates are clamped to each hard rubber cover. By means of the thumb-screws fastening each separate pair of elements, the carbon and metal plates can be changed rapidly and readily, either for repairs or renewal. The under surface of the hard-rubber cover is fitted with a soft-rubber cushion that prevents the spilling or splashing of the cell fluids when in process of transportation; the lid is further screwed down well into place by thumb screws. The cells, six in number, for the production of the induced current are entirely distinct from the rest of the battery, though contained in the same box, and can be, if desired, lifted out and transported separately. Altogether this makes a very compact and at the same time a very desirable battery; the great objection to these combination batteries heretofore has been their liability to be constantly getting out of order; but

this objection seems to be very fairly overcome in this battery.

A very valuable though simple addition to the hypodermic syringe has recently been made by Kern, of this city; this consists of a long, delicate needle, made entirely of aluminium. The great objection to the ordinary steel needle is that it is liable to be corroded by the impossibility of drying the canal of the needle, and that certain fluids corrode the metal rapidly. Frequently, even when good care is taken of the instrument, the needle is found occluded by rust, etc., thus rendering it useless. Aluminium not being readily attacked by the agents ordinarily employed in hypodermic medication, and not being at all influenced by the presence of water, makes, perhaps, the best material possible for the construction of the hypodermic needle, as by it any fluid or agent desired can be readily employed. We would suggest here that, even when in constant use, a hypodermic syringe should occasionally be treated with a few drops of glycerine, as this tends to keep the packing moist, and thus causes better suction in the piston head, a matter of considerable importance, especially when a small quantity of fluid is to be injected.

A new universal uterine scissors is shown also by Kern. This consists of a pair of blades jointed like the ordinary scissors, these blades measuring eight inches in length, slightly curved at the flat. To the ends of these a pair of scissor blades, one inch in length, and so finished on the points as to present a probed appearance, while at the same time a cutting edge is preserved to the extreme ends, are attached; the joint being on the regular hinge principle, the cutting motion is produced by the long blades upon which the scissors proper are mounted. From the cutting blades a wire runs down the convex surface of the long blade handles, passing through an eye just back of the scissor-blade joint on the long arm, and terminates in a ratchet mounted upon a spring, the spaces between the teeth of the ratchet being caught by a stationary bridge. By this wire the cutting blades can be placed at any angle as compared with the long arms of the apparatus, and satisfactorily worked. We should imagine this to be a very desirable scissors, not only for uterine work, but for operations in any locality where there is but little space for ordinary manipulation; it would seem to be particularly available in operations about the throat and nasal passages, the scissor blades working, as they do, at such a variety of angles.

Correspondence.

A Curious Case.

Ed. Med. and Surg. Reporter:—

Mr. Matthew Snow, a laborer; aged 23; weighs 175; strong, muscular; never was sick a day in his life. On the evening of May 26th, while lifting at a large metal wheel, suddenly felt something give way in his bowels, "felt something tear," as he described it, with sharp cutting pain;" he felt sick at the stomach but did not vomit; walked to his boarding house, some half mile; eat a hearty supper; slept well that night. Next day, 27th, being Sunday, walked about, eat his regular meals, felt no inconvenience but soreness in his bowels. At 7 o'clock P.M., after eating a hearty supper, became deathly sick and vomited. I saw him one hour afterwards; found him pale, vomiting, and suffering some pain below the stomach, on the left side. Pain referred to one spot, presenting much the symptoms of strangulated hernia, although he never had any rupture. Gave him brandy and morphia, and ordered warm fomentations over the bowels.

May 28th. Vomited all night; abdomen enlarged and slightly tympanitic; pain paroxysmal; pulse 100; temperature normal; passed urine freely; complains of being cold, but has no regular chill. Consultation with Dr. J. A. Ritchey, of Oil City. Treatment, hypodermic injection of ¼ grain morphia every four hours; turpentine stupes, ice, brandy and milk by the stomach.

May 29th. Still vomiting; pulse 100; temperature 99°; breathing 20; kidneys acting freely; abdomen more enlarged and quite tympanitic; tenderness all over the abdomen.

May 30th. Not suffering so much pain; still vomiting; stomach bulging up above sternum; lies on his back with legs extended; tympanitis increasing; pulse 100; temperature 99½; breathing 22. Treatment continued. Warm water injections.

June 1st. Pulse 104; temperature 101°; breathing 25; vomiting less frequent; not much pain; somewhat under the influence of morphia; still vomiting occasionally; lies on his back with his legs stretched straight down; can't be turned on either side or his knees flexed without causing great pain and vomiting.

June 2d, 3d, 4th and 5th. Condition much the same. Pulse ranging from 98 to 108; temperature from 101° to 103°; still having paroxysms of pain and vomiting.

June 6th. Bowels move freely; discharge very offensive, tinged with blood; pulse 104; temperature 102°; tongue dry and coated brown; swelling but little abated, if any. Treatment, morphia increased to ⅓ grain. Turpentine, glycerine and sodium mixture applied over the bowels with cotton; ice and milk in small quanties often repeated.

June 7th. Consultation; Drs. Ritchey, Davis, Egbert and Conners, of Oil City; pulse 100; temperature 102°; breathing 30; perspiring freely; tympanites increasing; stomach distended; ribs pressed out on both sides; lies straight on his back; legs stretched; head low; tongue dry; great thirst. Treatment, turpentine

and a mixture of quinine, nux vomica and aromatic sulp. acid; morphia increased to ½ grain doses hypodermically every four hours.

June 8th, 9th, 10th, and 11th. Much in the same condition; temperature and circulation vary but little; vomiting occasionally; kept comfortable under the influence of the anodyne; bowels moving; kidneys acting freely; tympanites increasing. Treatment continued.

June 12th. Patient much in same condition; urine examined; slight acid reaction; otherwise healthy.

June 13th. Consultation, Dr. Snowden, of Franklin; not much change; swelling increasing; circulation, temperature and breathing about the same.

June 14th. Consultation, Dr. Arters, of Oil City; ribs distended on both sides, more on the left; diaphragm pushed up; lungs crowded; heart misplaced; apex beating two inches above nipple; difficult breathing; says he "will burst."

June 15th. Stercoraceous vomiting, throwing up large quantities of fecal matter; pulse 110, temperature normal, breathing 30.

June 16th. Consultation, Drs. Ritchey, Davis and Coope; patient evidently sinking; pulse 120; temperature below normal; breathing 40; nails blue, skin dark, extremities cold; says he is dying; asks me to cut him open."

Passed a minimum sized trocar and canula in median line below navel; large quantity of gas escapes, with strong fecal odor, followed by near a quart of purulent serum; patient much relieved; says he will get well. Left the canula in until the next day.

June 17th. Patient much be'ter. Removed the canula; bowels moving freely; takes milk without vomiting; abdomen very little enlarged.

June 18th. Abdomen distended again with gas. Introduced a large trocar and canula; a good deal of gas escaped, but very little serum. Attached the aspirator pump and pumped into the cavity a quart of ten per cent. carbolized water. Repeated this two or three times, thoroughly washing out the cavity.

June 19th, 20th and 21st. Patient improving, but considerable diarrhœa, which was controlled with bismuth and tannin.

June 22d, 23d and 24th. Convalescing slowly.

July 6th. Forty days from the time of receiving the injury fully recovered, so as to be able to be sent home in a carriage, ten miles in the country. Now I have given you a history of the case and treatment. I have not given any opinion as to what the particular lesion was. Was it intussusception, or some one of the many internal hernias? Why did the patient assume the position of low head and legs stretched straight down, which position he kept through the whole course of his disease?

That the material vomited on the 15th day was fecal matter, all who were present will attest.

That the gas and purulent serum discharged by the trocar and canula had a strong fecal odor was evident to all of us.

All the medical gentlemen who saw the patient agreed that there was traumatic peritoneal inflammation. But as to the particular lesion which caused it, the question was undecided, and as we were cheated out of the post-mortem, it will remain a mystery unless some of your numerous readers will inform us.

Oil City, Pa. T. C. McCulloch.

News and Miscellany.

Society of Hygiene in Madrid.

On the 23d of last April, the King of Spain, accompanied by several Ministers of State, inaugurated the new Society of Hygiene in Madrid. Simultaneously the first number of the Society's Journal, the *Boletin de Higiene*, appeared. The object of the journal, as its name imports, is to keep its readers well abreast of all that is newest and most valuable in sanitary science.

Poisoning from Red Stockings.

Dr. J. Woodland writes to the *Lancet* that, having had his attention called to several cases of great irritation of the feet and legs, causing small pustules to arise and the skin to subsequently exfoliate, and suspicion being fastened upon red stockings which the patients wore, he carefully analyzed them. He found a tin salt which is used as a mordant in fixing the dye. He succeeded in obtaining as much as 22.3 grains of this metal in the form of the dioxide, and as each time the articles are washed the tin salt is rendered more easily soluble, the acid excretions from the feet attack the tin oxide, thus forming an irritating fluid.

Rusty Surgical Instruments.

Apropos of this unpardonable practice, which is still occasionally observed even among good surgeons, the *Lancet* says:—

In a highly sensational and unduly colored sketch, a writer has described in *Knowledge* a case of ascites, to which, some years ago, he called in "the great master of British surgery, Sir Rusty Poyntz," who, on being requested to tap the patient, produced for the purpose a trocar with dull point, rusty sides, and an ill-fitting canula, and, in spite of protest, insisted on using it, pleading, "It don't signify, you know." We cannot pretend to dispute the bare facts of the case, but we may fearlessly assert that no "master of British surgery," great or small, would to-day be found who would perpetrate such a cruelty. But yet there may be quite room even now for a word of warning as to the importance not only of absolutely clean, but of very sharp-cutting instruments. Where anæsthesia is not employed the amount of pain saved by using a knife of the greatest attainable keenness is very great, while in all cases alike, attention to this particular is one of the requisites of the successful surgeon who would obtain speedy healing of wounds. It is not an unknown thing to see two or even more incisions made before skin is divided, and the result must of necessity be a partially bruised and irregular edge, the healing of which is in exactly that measure interfered with.

Comparative Size of Drops.

The following table approximately gives the average number of drops in a *fluid drachm* of the various classes of U. S. P. preparations:—

Sulphuric ether	174	Mixtures	89
Fluid extracts	141	Vinegars	77
Spirits	141	Syrups not containing fluid extracts	69
Tinctures	136	Solutions (1 exception)	66
Volatile oils	131	Diluted acids	61
Oleo-resins	124	EXCEPTIONS:	
Acids (3 exceptions)	123	Sol. nitrate of mercury	131
Wines	106	Nitro-muriatic acid	76
Fixed oils	103	Muriatic acid	70
Syrups containing fluid extracts	97	Sulphurous acid	59

Flowers for Hospitals.

We are glad to note the "*flower service*" (as it is termed) which obtains in England. On a recent day the church of St. John, at Paddington, was the scene of one these "*flower services*," when the chancel was one mass of flowers and fruit, the offerings of children to the sick in the hospitals. This is a most excellent example to follow in this country.

Vivisection.

The following communication to the *Lancet* of a recent date is interesting, on account of the violent anti-vivisection excitement that is now agitating England:—

SIR:—In the *Times* of this morning there is an account of the State ball given by command of Her Majesty, at Buckingham Palace, last evening. Among other announcements of the dresses worn by Royal and noble ladies is the following: "Her Royal Highness, Princess Christian of Schleswig-Holstein, wore a dress of white satin and tulle, trimmed with bunches of pale pink roses and *humming birds*. I, of course, was not present, but I can imagine the panic that Her Royal Highness's appearance must have caused among the sympathizers with the anti-vivisection agitation! Surely some of them must have been ready to swoon away at such a parade of slaughter—such a holocaust at the shrine of the Goddess of Fashion.

Pen Picture of Pasteur.

M. Pasteur is described as a man of low stature and powerful frame—spare, angular, and weather beaten. Of humble origin, the son of hard-working parents, he bears the indications of his race and hereditary bias in every lineament of his countenance and every movement of his well knit, muscular physique. He is a man of few words, abrupt but clear in his sentences, logical, and to the point. His style of speaking is what would be ordinarily called argumentative; his voice is clear and distinct, but unemotional, and his gestures are quick and impetuous, although wanting in the elegance that arises from early training. It is a very curious fact, but one that finds its correlative in the lives of Wallace, the celebrated British naturalist, and Professor Crookes, the great master in physics, that, although his fame rests upon minute researches of the most material complexion, M. Pasteur is an ardent and steadfast believer in spiritualism. He takes no interest in the positivist doctrines of Comte or in the evolution theories of Herbert Spencer, who, he thinks, overlook the central fact of the universe, infinity. Like M. Littre, he holds that without a spiritual link the human family would fall to pieces and nations degenerate into barbarian hordes. In his own neighborhood, M. Pasteur is a man of political and social weight, and in his own house he is the soul of genial and pleasant hospitality.

Items.

Errata.—On page 213, first column, line 23 from bottom, for *water* read *alcohol*.

—Dr. J. W. McLane, of New York, does not place much reliance on a skimmed milk diet for albuminuria.

—"What is the action of disinfectants?" was asked of a medical student. "They smell so bad that people open the door and fresh air gets in," was the reply."

—"I wouldn't be in Egypt," said Mrs. McGill, last week, "for all the wealth of Creosote." Seeing a look of astonishment in the faces of her auditors, she added: "Creosote, you know, was an old Roman god, and everything he touched turned into gold."

—Dr. Riembault, in a communication made to the Paris Academy of Medicine, states that he has made a series of researches with reference to "miners' anæmia," and he believes that this affection is due to the presence of a worm of the filaria species, and not to that of the *ankylostomum duodenale*, as asserted by M. Perroncito, of Turin.

MARRIAGES.

HUTTON—WOODWORTH.—At Fergus Falls, Minn., July 11th, 1882, Dr. Terry J. Hutton and Miss Hattie J. Woodworth.

CHAMPLIN—SHERWOOD.—In Syracuse, N. Y., July 12th, by Rev. Henry W. Sherwood, Henry W. Champlin, M.D., of Chelsea, Mich., formerly of Orwell, Pa., and Delia A. Sherwood, of Owego, N. Y.

LOVELAND—STERLING.—On Thursday, Aug. 3d, 1882, at the Calvary Presbyterian Church, West Brighton, Staten Island, by the Rev. Theo. A. Leggett, Dr. T. O. Loveland, of Boston, and Bessie May, daughter of Erasmus Sterling.

McCLELLAN—YOST.—On Tuesday evening, Aug. 1st, by the Rev. Lawrence Guerin, at the residence of the bride's parents, 233 Garrard street, Covington, Ky., Dr. James S McClellan, of Bellaire, O., and Miss Lillie V. Yost.

WEEKS—UMSTEAD.—On Wednesday, Aug. 2d, 1882, by Rev. F. C. Pearson, Dr. Albert Weeks, of Phœnixville, and Miss Mary E. Umstead, of Pottstown, Montgomery county, Pa.

DEATHS.

DE GRAW.—At San Francisco, Cal., July 26th, in the 46th year of his age, Dr. Charles S. De Graw, of New Jersey, formerly Assistant Surgeon, U. S. A.

JACOBY.—On the 7th inst., at Sumneytown, Montgomery county, Pa., Henry S. Jacoby, M.D., son of the late Daniel Jacoby.

LOMBARD—In Colebrook, N. H., July 8th, E. D. Lombard, M.D., aged 47 years.

MUSSEY.—In Cincinnati, O., Dr. Wm. H. Mussey, Tuesday, Aug. 1st, in his 64th year, of apoplexy.

SOUTHWORTH.—In New York, on Tuesday, Aug. 15th, Edward Southworth, M.D., in the 24th year of his age.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

THE LANCET IN DENTITION.

BY THOS. S. SOZINSKEY, M.D., PH. D.,
Of Philadelphia.

It is noted by Southey, in his common-place book, "The Doctor," that "Progers, who had been about the person of Charles the Second, died at ninety-six, in cutting his teeth. He had four, and many others were coming, which so inflamed his gums that it proved fatal." Poor old Progers! "Cutting of the teeth" is, rightly or wrongly, credited popularly, with the destruction of many lives, and it would seem from this case that it is liable to be accused of being at work even in the terminal stage of existence. In the nursery it has always, perhaps, been regarded as a very serious matter. Nevertheless, this common belief, like many another, may not be well founded. Cumulative tradition has possibly served to, at least excessively emphasize the balefulness of the process. It may, however, be taken for granted, I believe, that the amount of suffering experienced by children in general while getting their primary teeth is very considerable. It causes decided uneasiness in almost all, and decided danger in some. If it rarely or never destroys life directly, it certainly not unfrequently does indirectly. But I am not sure that it is entirely wrong to give it as the actual cause of death in not a few cases. This is at any rate done. In Philadelphia, about thirty deaths are attributed to it, on the average, yearly, in the bills of mortality. During the census year ending June 30th, 1870, there were three thousand two hundred and forty-seven deaths attributed to it in the United States. There is assuredly some ground for the prevailing belief that dentition is the direct or indirect source from which flow many of the ills and a large share of the mortality of babies.

It would appear, however, that there are some physicians who seriously regard the coming of the teeth as an extremely innocent matter, being, as they say, a purely physiological process. I would advise such that it is assuming a great deal to take it for granted that dentition is in all cases a purely physiological process. Perhaps in no child is it absolutely physiological; it is at best only approximately physiological. In a recent address, Dr. B. W. Richardson went so far as to declare that he "had never seen a healthy child," never one "that had not in it either some actual or latent constitutional disease." At any rate, there is good reason for believing that in a large proportion of children, especially in large cities, dentition is of decidedly pathological import. As is true of many other troubles, it generally tends to be more marked in proportion to the degree of unhealthiness of the child. And let it be borne in mind that the sensibility of all infants is great, and of some sickly ones such that even a trifling irritation may be followed by serious constitutional and other effects.

But it is not my purpose to speak of the subject of dentition. This has been done very well in a lecture published in this journal recently. It may be well, however, to say, in the words of John Hunter, in his admirable treatise on the natural history and diseases of the teeth, "the symptoms are so various in

different children, and often in the same child, that it is difficult to conceive them to be from the same origin, and the varieties are such as seem to be beyond our knowledge."

Now, when to the discerning senses of the observing, sensible physician a child is suffering severely from the eruption of one or more teeth, relief should, of course, be procured as soon as possible. How is this end to be attained? The advice given by many amounts to little more than to use a soothing-syrup—a la Winslow—of some sort. Meeting the various indications is, in truth, in numerous cases, far from being an easy matter. Such measures as serve to favor the general health are particularly indicated in every case. Careful regulation of the diet, daily bathing and a fair amount of exercise, especially in the open air, are among the items of great significance. Make the process as little pathological as possible by making the condition of the child as physiological as possible. Anodynes, antacids, febrifuges and other remedies, including local applications, may or may not be called for. But I believe the remedy most imperiously called for, in at least bad cases, lies in the use of the lancet.

Of the use of the lancet in dentition it is curious to observe how different are the opinions entertained. Some do not hesitate to say that it is of no value. Thus, in a recent widely circulated work on the diseases of children, by Dr. Henoch, a Berlin practitioner of seemingly large experience, it is said: "It is now generally held that every attempt to facilitate the eruption of the teeth, and thus remove the symptoms due to difficult dentition, is absolutely useless. I have in earlier years performed scarification with sufficient frequency to convince myself of its entire inutility; and it even appears to me that the cicatrix formed may increase the difficulties connected with the penetration of the teeth." Here is what Dr. J. Lewis Smith says on the subject, in his work on the diseases of infancy and childhood: "The gum-lancet is now much less frequently employed than formerly. It is used more by the ignorant practitioner who is deficient in the ability to diagnosticate obscure diseases, than by one of intelligence, who can discern more clearly the true pathological state. Its use is more frequent in some countries, as in England, under the teaching of great names, than in others, as France, where the highest authorities, as Rilliet and Barthez, discountenance it. . . . . I know no accidents of dentition which require prompt scarification, except suppurative inflammation of the gums, convulsions, and paralysis. In other cases the operation may be safely postponed till other measures have been employed." In Drs. Meigs and Pepper's treatise on the diseases of children it is said: "Lancing of the gums is undoubtedly a most important point in this [laryngismus stridulus] and other diseases of childhood connected with dentition. We have long been convinced, however, from personal observation, that a resort to this operation merely because the child is passing through the period of dentition is at least useless. We have never found it to do any good unless the teeth are near enough to the surface to produce manifest swelling, attended with heat and soreness of the gums. So long as the gum is hard, insensible, not turgid, and of its natural color, and the mouth not hot, cutting has done no good." That wise old master of the healing art, John Hunter, after speaking of symptoms arising from dentition says, "So far as my experience has taught me, to cut the gum down to the teeth appears to be the only method of cure."

Truly the authors quoted from differ sufficiently as to the value of the lancet in dentition. It is worth while to dwell a little on what they say.

Dr. Henoch speaks very rashly, to say the least, in declaring that "it is generally held that every attempt to facilitate the eruption of the teeth is absolutely useless." The idea was not formed from an extensive acquaintance with the literature of the subject. Again, the statement of the Doctor as to his experience with the use of the lancet may well lead one to infer that he has had hardly any experience with it. He is like those who, although having no knowledge of the use of the lancet in general medicine, yet unhesitatingly venture to condemn it. What he has to say about "the cicatrix" may rightly produce the impression that he has not made himself master of the subject. If the lancing is properly done, there need be no cicatrix; and if there be one it will not serve to retard the "penetration" of the tooth. As Hunter long ago said, at the point of cicatrix the gum offers the least resistance to the appearance of the tooth.

Dr. Smith is doubtless right in holding that ignorant practitioners are very apt to use the lancet when not required, and in his intimation, that the use of it is largely a matter of fashion. But I am also quite sure that too many practitioners who are usually regarded as intelligent do not use it as often as they should. His statement that he "knows no accidents of dentition which require prompt scarification, except suppurative inflammation of the gums, convulsions

and paralysis," is a trifle extraordinary. What of cases of, say, laryngismus stridulus and of cholera infantum, in which dentition bears largely a causative relation? Except in the diseases he mentions, the Doctor would postpone the operation "till other measures have been employed." It scarcely follows from this that he is acquainted with the cardinal principle of sound medical practice. In treating of the same subject, Hunter correctly remarks, "It would be better at once to remove the cause, than to be attempting from time to time to remove or palliate the effect." Wasting time trying to palliate effects, while the cause is allowed to act, lets many a little innocent go unnecessarily and speedily into the grave.

Drs. Meigs and Pepper "have long been convinced, from personal observation, that a resort to the operation merely because the child is passing through the period of dentition is at least useless." It is rather strange that they were ever otherwise than "convinced." No sensible physician cuts a child's gums indiscriminately. Resorting to the lancet when there is no evident need for it, no matter how the child is affected, is, as Dr. West fitly says, "barbarous empiricism." The idea that it is the approach of the teeth "near to the surface" which produces the troubles which are met with in dentition is not of necessity a truth. At least the main source of trouble in the appearance of a tooth is not at the surface; it is at the base. The backward pressure on the sensitive nerves and other parts gives rise largely to the pain and irritation about the gum. This backward pressure may set up trouble a considerable time before the tooth nears the surface, the tension then being almost or quite as great as later. In fact it often, or perhaps I should say generally, happens that there is a spell of trouble some time before the tooth is about to make its appearance. In some it is very marked and it may be repeated. The capsule becomes distended and the surrounding parts hyperæmic and painful, and there is a free flow of saliva. In any case where there is evidently decided irritation about the gum the lancet should be used. It should be used even if for no other reason than to relieve the child of local pain, of toothache, an affliction which, as many know, and Burns told in expressive poetic phrase, is something awful enough in itself, a pain which at its worst Bacon had reason in believing to be "one of the sharpest of pains." There need be no hesitancy in using the lancet repeatedly if the gum is at any point tense and angry looking. Says Hunter, "I have performed the operation above ten times upon the same tooth, where the disease had recurred so often, and every time with the absolute removal of the symptoms."

That the lancet will afford relief in the presence of very marked symptoms every one surely is aware who knows how to use it. It is an instrument by which much may be done to lessen suffering, cure disease and save life. Here is a delicate child, somewhat over a year old, languid, pale, the victim of one or two convulsions, with contracted brows, a temperature of from 101° to 102°, a tendency to diarrhœa, and a slight bronchitic cough. I lance his cutting tooth, and within a few hours he is almost entirely well. I have done the thing so often in his case that I know precisely what the result will be. This lymphatic child of fifteen months has a developing croup; the hurried breathing, the noise in the throat and all the other symptoms are becoming decided. I lance his appearing eye teeth and he begins immediately to get well. There is a strong looking boy, nearly two years old, with a temperature of 103°, and a marked cold on his chest. I prescribe appropriate remedies but at the end of two days he is no better. I lance a pair of coming molars, and next day there is no fever hardly, and the cough speedily vanishes. That poorly cared for child, who has about completed her first year, is evidently, from the high fever (103.5°), nausea and tendency to diarrhœa, drifting into the fatal grasp of cholera infantum, the midsummer heat favoring the development of that serious infantile disease. I look at her mouth and find that the gums over both the eye- and the stomach-teeth are tense and angry looking. I lance these points, and very simple measures restore the patient, within forty-eight hours, to her usual state of health. But I need not give an extended recital of cases. I am of the opinion that early, and, if need be, repeated lancing would save many who should otherwise perish from convulsions, bronchitis, cholera infantum and other diseases. Especially in spent children, in the warmer part of the year, should there be no delay. Statistics of the census year ending June 30th, 1870, show that there are more deaths attributable to dentition in the third quarter of the year than in the two preceding ones together, and many more than in the first and fourth together. The Philadelphia bills of mortality present a very similar showing.

In order that lancing the gums may do as much good as possible it must be done well, but, of course, not butcherly. A plain incision with

a very sharp lancet is not enough; it will generally do only a little good. This is what is not uncommonly done. Let there be several more or less irregular incisions made, with a somewhat dull lancet, and the hoped for result will very certainly follow. In bad cases the gum should be very thoroughly scarified, so thoroughly that there will be little or no likelihood of the parts uniting over the tooth. And it is proper to extend the incisions well to the sides of the coming tooth. This may be called for after the tooth has partly appeared. Whatever bleeding occurs will be beneficial; it will serve to relieve the hyperæmia and pain. In fact, in not a few cases it is the bleeding that is principally called for; local depletion affords immediate relief. It will not be harmfully profuse, likely, in any case. Says Hunter, "I never saw a case where the bleeding proved either inconvenient or dangerous."

What harm may result from lancing the gums, under any but very extraordinary circumstances, it would be hard to state. I do not feel sure that it can do any, and in this belief I am fortified by the opinions of perhaps all dentists and others who have carefully studied the matter. It may cause temporary pain. Still, this is not very marked. Many a child will open its mouth and have several teeth thoroughly lanced without giving a whimper. As for the tenderness of the gum, which there may be for a day or two, from thorough lancing, it is comparatively a small matter. The idea that lancing will retard the development of the tooth has, I believe, no just foundation. It would appear to be based on the erroneous notion that when lancing is practiced the tooth should immediately appear. It is probable that in no case is there any more than an apparent delay. As already stated, the irritation about the gum which calls for the use of the lancet may arise weeks before the tooth approaches the surface. A tooth does not receive its nourishment from the structures above or about its crown. The cicatrix and hemorrhage I have already spoken of at sufficient length. In all proper cases the lancet may, then, be used, with confidence that it is a markedly non-injurious, as well as an almost infallible means of relief.

—In Berlin, has been formed a society similar to the English Ambulance Association. It was done at the suggestion of Prof. Esmarch, and the Empress has accepted the "Protectorat." The intention is to have, in cases of accident, all necessary professional and other needful service rapidly on hand.

ANEURISM OF AXILLARY ARTERY, FOLLOWING LUXATION OF HUMERUS.

REPORTED BY V. KERSEY, M.D.,
Of Pittsburgh, Pa.

Notes of the following interesting case were furnished by Dr. Jos. Dickson, of Pittsburgh, Pa.:—

Levi P., aged 24 years, farmer, of previously good health, sustained a sub-coracoid luxation of the right humerus, on October 27th, 1878. He was in the act of stepping over the "tumbling shaft" of a threshing machine, when he tripped and fell, the revolving shaft catching his clothing and carrying him around a number of times. Dr. K., of Evansburg, Pa., saw the patient within a short time, and discovered a sub-coracoid dislocation of the humerus. He effected reduction without much difficulty, by the following manipulation:—

The arm being raised perpendicularly to the body by an assistant, the doctor placed his left hand, thickly enveloped in the folds of a towel, in the axilla, and at the same time made forcible counter pressure with the right hand over the acromion.

Since the time of the injury patient states that he has felt "something hard under the arm;" six weeks ago he discovered a lump in the axillary space, and three weeks ago he noticed it pulsating, or "beating, like his heart." On January 4th, 1879, he consulted Dr. Dickson, who stated to him that he was suffering from an aneurism of the axillary artery, and advised him to begin treatment at once. To this he consented, and it was decided to try the effect of digital compression. He was previously prepared, by light diet and free purgation, and on January 6th, at 1.20 P.M., he was placed in bed. At this date the tumor was the size of a small orange, located in the centre of the axillary space, painless, pulsating, and possessing a marked bruit.

He states that in the first week of its existence its growth was quite rapid; later, it grew more slowly. His sufferings, which have not been excessive, consisted of wandering pain shooting down the arm and across the chest.

The axillary temperature of the two sides varied one degree, that of the right being higher.

Radial pulse of right side was weaker than the left. He was placed in a recumbent position, and the supra-clavicular region of right side dusted with subcarbonate of bismuth. One fourth grain of sulphate of morphia was administered by the mouth.

Digital compression, made by the thumb of the assistants, of which there were several, was ef-

fectual in controlling pulsation in the tumor. The hand of the assistant grasped the shoulder of the patient from behind, and the thumb pressed upon the subclavian artery, at the point where it crosses the first rib. Pressure, by means of the assistants present, was thus maintained steadily for eight hours. Occasional doses of morphia were administered, when he complained of pain. At the end of this time no pulsation could be detected in the tumor, and pressure was removed. He was advised to remain in bed for one week, and to carefully avoid exercise for several weeks. After a few directions concerning his diet and drink, he was dismissed as cured. No more was seen or heard of him until January 9th, 1879, when he presented himself with the tumor again pulsating.

The axillary temperature and the pulse were identical upon the two sides. The tumor was smaller, firmer and denser than when first seen, but is pulsating quite perceptibly and possesses a marked bruit.

He was again placed upon spare diet, and subjected to free purgation, and on January 17th, with previous preliminaries, systematic digital compression of the subclavian was a second time commenced.

The pressure was so applied as to check all pulsation in tumor, and in the arteries below. When pressure was begun, patient complained of sense of fullness about the head and face, and numbness of arm and hand. Morphia sulphate was administered during the first twenty-four hours, as needed to quiet pain. Tinct. veratrum viride (Norwood's), was administered in two minim doses, hourly, to reduce the pulse-rate; its use was discontinued when pulse-rate fell to 100 beats per minute.

His nourishment consisted of half a pint of warm milk and bread every six hours. He was allowed very small amounts of water. At the end of twenty-four hours, when all pressure was removed for a few moments, the radial artery could be felt faintly pulsating, although no pulsation could be discovered in the tumor.

January 20th, auscultation revealed a loud and distinct bruit in that portion of the tumor opposite the central division of the pectoralis major muscle. This bruit was only noticeable after pressure had been removed for several minutes.

On January 24th, one week after commencement of second period of treatment, all pressure was removed; on this day the tumor was quite small, and, except a great numbness and lack of power in the arm, he was practically well. In one week he had so far regained the use of his arm as to be able to feed and dress himself without assistance; he was discharged from treatment.

On January 2d, 1882, patient presented himself at Dr. Dickson's office, and was carefully examined by Dr. McCann and Dr. Dickson. Nothing of the tumor could be found, and patient stated that the limb was "as good as ever."

COLD TREATMENT OF SCARLATINA.

BY JAMES Y. SHEARER, M.D.,
Of Sinking Spring, Pa.

Read before the Berks County Medical Society.

Mr. President and Gentlemen of the Medical Society of the County of Berks:—

In obedience to the wishes of the Society I appear before you, to address you on a subject of great importance, viz., cold water or ice in the treatment of scarlatina. When men of eminent skill in the profession differ so widely in their views as on this subject, there must be something of so great an importance attached to it that it cannot be overrated. Such a dreadful scourge as scarlet fever, which carries away its victims by the thousands and fills the land with mourning, ought to be studied and sifted with the closest attention. When we consider the fatal nature of this disease, we should not hesitate to resort to the best and safest remedy, no matter what our choice treatment may be. I consider it the duty of the practitioner to gather all the information relating to the treatment of scarlatina, coming from a reliable and trustworthy source, that he may be able to acquire.

I have no hesitation in saying that the ice-treatment in scarlatina is preëminently proper. My own experience during the last fourteen years fully convinces me of the truth of this assertion. It is true this treatment has met with some opposition in the ranks of the profession. Some doctors seem to be unwilling to accord to it the merits which I think it deserves. There are different reasons for this unwillingness. First, their prejudice prevents them from using it, and in the next place (when they do use it) they lack discretion in its application.

In the May number of the *American Journal of the Medical Sciences* for 1833, there appears a communication from Dr. Samuel Jackson, of Northumberland, Pa., in favor of the cold or ice treatment in scarlatina. I believe Dr. Jackson first advocated *in print* this treatment in this country. Great credit is due to him for venturing to advocate in print a practice or treatment which was condemned generally, not only by the

laity but by the profession as well. Dr. Chapman, of the University of Pennsylvania, in 1826-27, vehemently opposed this treatment in his lectures to the students. But Dr. Hiram Corson, of Conshohocken, Pa., although having listened to those very lectures of Dr. Chapman, and having imbibed the false doctrines imparted to him, about a year thereafter, in the face of a perfect storm of opposition, used cold water in scarlatina with the most happy results. Before giving my mode of treatment, let us glance for a moment at the disease.

It is well settled that scarlatina is divided into *scarlatina simplex*, *scarlatina anginosa*, and *scarlatina maligna*.

In scarlatina simplex the fever is seldom active ; the cutaneous efflorescence is complete, but there is scarcely any inflammation of the throat.

In scarlatina anginosa the febrile excitement is greater, the eruption is complete, and there is always inflammation of the throat.

In scarlatina maligna the fever is of a depressing character, with considerable depression of the vital forces, and besides the other symptoms of scarlatina in general, a sloughing inflammation of the throat.

In scarlatina anginosa there are always the usual symptoms of pyrexia, preceded by a peculiar lassitude. The affection of the fauces is always prominent ; stiffness of the jaws, soreness of the throat, and pain in swallowing, are often experienced in the commencement. The inflammation of the fauces advances with the progress of the disease, and patches of a concrete exudation are generally seen on the surface of the tonsils. In adults a strong chill is the first symptom ; in children, a violent convulsion or a succession of them, or a severe attack of vomiting, with prostration. The eruption makes its appearance at the end of the first, or the beginning of the second day. As vomiting greatly prostrates the patient, a great deal of it shows the severity of the disease. The heat under the tongue is very great. In fact, the temperature in this disease exceeds that in every other fever. It is affirmed by some writers that in some instances it arose to 112 degrees, Fahr.

I have used cold water in scarlatina for upwards of twenty years. In May, 1862, I was called to see a little boy about ten years old, who had a very severe attack of scarlet fever. I found him in convulsions and unconscious, from the very high fever. After a careful examination of the patient, I made up my mind that the boy would die, and so apprised the family. I concluded that the only way to give relief to the patient was by reducing the temperature, and to do it promptly and effectually, I stripped the boy and sponged the whole body with cold water. In less than thirty minutes the convulsions ceased, the temperature was very much reduced, the patient had rest, and both the family and myself had hopes of the boy's ultimate recovery. The fever, however, commenced increasing shortly after the cessation of the sponging, as expected, and in about two hours convulsions again set in. I was promptly sent for again, and repeated the sponging with the same result. This had to be done at least six times before breaking the fever effectually, with the period of time increasing between each interval.

Every time when the convulsions ceased the boy told me how good the cold water felt, which I considered strong evidence of the counteraction which the cold water produced upon the high fever. Before the first application was made the eruption had a bluish color, but after the application of cold water it assumed a red, normal hue. The recovery of the patient was speedy, and this without anything else except a little sweet spirits of nitre. To make the efficacy of this treatment more convincing to me, I was called to see a child of about the same age, about two weeks thereafter, that had scarlet fever, and was suffering in the same manner. This was exactly a parallel case—the same in all its bearings. The parents positively refused to let me touch the child with anything cold. I told them the great danger their child was in, and my unflinching confidence in the cold water treatment ; but all without success. They persisted in having their own way. I resorted to all means recommended by the authors, but all my efforts were futile, and the child died. I have never been shaken in my steadfast opinion that if I had been permitted to treat that child according to my wishes and inclinations, with cold water, I could have saved its life.

During an epidemic in 1868 I treated forty cases with ice and cold water, and was successful in all except one case, and that was a very weak and puny child, only six months old, and otherwise deformed.

Two years ago I attended a family who had only two children. Both were taken sick at the same time, with scarlatina. I at once noticed the malignancy of the disease, and knew that I was wrestling with a foe that required prompt and heroic action to subdue. The throats were swollen, having gangrenous spots, accompanied by great physical prostration ; in fact, the patients were fast approaching the threshold of

eternity. Both parents and grandparents were opposed to the ice treatment, arguing that it was an application for the *dead* and not for the *living*. I, however, explained to them the theory of the ice treatment, and they, being intelligent people, yielded to my importunities. I at once applied ice externally to the throats, gave them ice to eat and cold water to drink, and in less than ten hours relief was apparent, and in twenty-four hours they were beyond serious danger. Although it took two weeks to restore them fully to health, I have no doubt in my mind that without the use of ice neither one would have recovered.

The mother took it also, and in a violent form. In the case of her children she strenuously opposed the use of ice; but in her own case, having seen the good results of it in the cure of her children, she manifested not the slightest opposition to its use. After applying it to her throat, and using it with care, she realized such good results that she cannot speak too highly of it. These are only some of the many cases I might mention, and which I treated with similar success.

During the last year, I have treated some forty cases of scarlatina, and only four of my patients died; and in these four cases the parents would positively not allow me to use ice.

My mode of applying ice to the throat is not on the bare skin, but have a muslin between the skin and the ice; and great care should be taken to get it to the inflamed glands of the neck. Place it between two bandages of muslin, and then apply it to the glands, tying the bandages over the crown of the head.

In all my cases in which I used ice, there were no sequelæ.

During the last twenty years of my practice I have, in scarlatina, uniformly followed the treatment just described, except in some few cases when the parents' opposition to it prevented me, and my success has been such as not only gave me great satisfaction, but it has been so invariable, that I feel it my duty not only to recommend it, but to appeal to the profession to give it a fair and impartial trial.

GHEEL.

An abstract of a paper read before the Medical Society of the State of Pennsylvania,

BY S. S. SCHULTZ, M.D.,

Of Danville, Pa.

Gheel had its origin as a place for the abode and treatment of the insane, some twelve or thirteen centuries ago. The belief then first became current that presence at the shrine of St. Dympna, who was murdered in a fit of maniacal fury by her father, an Irish king, from whose unnatural passion she had sought shelter in Belgium, cured convulsive diseases and insanity. This superstition brought the insane from far to be cured at this place, and they were, for the sake of charity and money, received into the homes of the peasants, and those who now form the class of inhabitants called guardian nurses may be literally taken to be their descendants.

The commune and borough of Gheel are divided into four sections, each of which, with many exceptions, receives only a particular class of patients, and is in charge of a physician who visits them once a week, and of a supervisor who makes his visits once a day. The 1200 or 1500 patients are scattered through the commune, which is some seven miles square. From one to four are received into one house.

Some of the houses are capacious and comfortable; others—and about twelve and a half per cent. of the patients are accommodated in such—are very humble and destitute of comfort and the necessary appliances for taking care of the sick. Floors are of clay or brick, roofs thatched, and sleeping places are reached by ladder, and are often immediately under the roof and without windows. One place on the first floor has often to serve for sitting and dining rooms, kitchen and wash-house for the entire family, sane and insane. Such places are on the outskirts of the colony, and are not usually reached by ordinary visitors. During the autumn chills and fever are, in such quarters, frequent, both among nurses and patients.

The mass of patients, no doubt, have great freedom, but others are restrained in a way that would be considered very objectionable in an ordinary hospital, and would not be necessary.

Not all classes of the insane are received, but only such as are best adapted to the family treatment, and Gheel could never take the place of an ordinary State hospital, on this account.

In order to accommodate such as become temporarily excited or dangerous, and those who get there in violation of the rules,* an infirmary has, in recent years, been built, not differing essentially from an ordinary hospital for the insane. This surrenders the idea that family treatment is suitable for the insane as a class.

Patients being so widely scattered through the township makes efficient supervision impossible, and such supervision is absolutely necessary for

* Excluding the dangerous and otherwise objectionable.

the proper care of any dependent class, and especially the insane.

A second Gheel, even if it were desirable, could probably never again be established. It had its origin in a peculiar combination of circumstances, without which it could not have originated, and which are not likely to occur again.

A CASE OF ACUTE HYDROCEPHALUS.

BY CHARLES F. SPANGLER, M.D.,

Of York, Pa.

(Read at the Session of the York County Medical Society, July 6th, 1882.

Modern scientific investigation concerning affections of the cerebral organs have demonstrated that acute hydrocephalus, of the idiopathic character, is of rare occurrence, and that nearly all of the so-called cases have now been ascertained to be instances of tubercular meningitis.

Meningitis with an abundant serous effusion has been called acute hydrocephalus, and older writers, including Beddoes, Condie, Cullen, Thomas, Watson and others, invariably employed the term synonymously with inflammation; but the term should be limited strictly to a non-inflammatory, non-tubercular or dropsical affection.

The arachnoid being analogous to other serous membranes of the body, is subject to like pathological conditions, producing abnormal aqueous secretions proportionately as the intercranial vessels present anatomical and functional peculiarities. And it is not impossible that a disturbing agent exists, so affecting the cerebral blood current as to produce an abnormal exudation of serum. This occurs in chronic hydrocephalus, and it is when the morbid action manifests its influence in a greater degree of intensity that we have the acute form of the disease.

The case which came under my observation in May last was that of a white male child, aged 20 months, of fine, robust appearance, and of unquestionable antecedents. Had always enjoyed good health prior to the above-mentioned period, when the following features were presented, viz.: The child appeared dull, drowsy, with indisposition to exertion, indifference to surrounding objects, and impaired muscular coördination, the temperature and pulse indicating a fever of moderate intensity; tongue thinly coated with a whitish fur; anorexia, nausea and constipation, with a short, dry cough, continuing thus for about forty-eight hours, when there was a decided improvement, the patient appearing apparently well. Physical exploration of the chest revealed a normal lung and heart, with the exception of a mild form of bronchitis. However, during the night of the third day symptoms of greater gravity became manifest. There was evidence of cephalalgia, great restlessness, flushed countenance, injected conjunctiva, contracted pupil, and the retinæ morbidly sensitive to light, the skin hot and dry, temperature elevated, pulse full and rapid, respiration hurried, active delirium, convulsions and left-sided hemiplegia. Synchronously with the onset of coma and hemiplegia was a conspicuous decline in the temperature, in the frequency of the respiratory movement and cardiac pulsations: the palpebræ remained unclosed, the pupils dilated, the eye no longer is over-sensitive to light, and almost complete anæsthesia of the surface is present.

The symptoms of active hyperæmia gradually gave way to those evincing pressure upon the hemispheres. The coma becomes more profound, the hemiplegia more decided, the respiratory movement more enfeebled and interrupted, until the sixth day of the disease, when death occurred. During the later stage of the malady, when the child was raised to the sitting posture, the head falling forward upon the chest or backward upon the pillow, a distinct gurgle or splashing sound was elicited by the fluid propelled against the walls of the cranium, audible at a considerable distance from the bedside. This phenomenon was reproduced even after death.

The head was well developed and in proportion to the general contour of the body. The bones of normal density, strongly sutured, and the fontanelles nearly obliterated. Unfortunately, an autopsy being unattainable, the anatomical characteristics could not be ascertained, but the nature of the lesion is reasonably indicated by the suddenness of the attack, occurring in a previously healthy subject of good family history, in which, owing to defective intercranial blood supply, from whatever cause, there ensues congestive symptoms of a passive character, continuing for a time, with a period of remission, followed by an active congestion, the symptoms of which are rapidly superseded by those of pressure from the extravasated serum.

The accumulation of the fluid being almost simultaneous with the occurrence of hyperæmia and the overwhelming effects of the abundant effusion in arresting the elements of vitality, justly ascribe the case as one of acute hydrocephalus, unconnected with tubercle or inflammation.

The treatment during the earlier stage was purgation followed by potassium bromid. in combination with the tincture of the root of aconite, continued throughout the hyperæmic condition, in conjunction with cold to the head and warmth to the extremities. When evidence of effusion was perceptible the compound solution of iodine was administered in suitable doses, with inunctions of mercury.

DIPHTHERIA; ITS ETIOLOGY AND TREATMENT.

BY H. L. GETZ, M.D.,
Of Marshalltown, Iowa.

In your issue of February 4th, 1882, appeared an article, under "Special Reports," on Diphtheria, which I wish to commend, and upon this subject express my views.

Concerning the seat of the disease there can be little doubt; nay, there can be no doubt in the minds of those who have had experience with the disease, that if it is not a constitutional disease at the outset, it very soon becomes such. And if the disease is communicable through drinking milk, etc., while micrococci may attach to the fauces and tonsils, and thence originate the disease, it is quite as likely that some may be and are carried into the stomach, and so on into the circulation. And in such an event it would be possible for the disease to be sometimes first constitutional and at others first local. In either event, if the disease germs are lodged anywhere in the system, local or otherwise, the constitutional and the local symptoms will soon be manifest; so that the treatment resolves itself into local and constitutional, from the outset. At any rate, this is the only safe mode to adopt. In some instances, if the disease were purely local (which I believe it may sometimes be), and we had some means by which we might to a certainty settle this point, we might then adopt a purely local treatment, perhaps with success, if the cases were recognized in their incipiency; but having no such means we must be alike prompt in local and constitutional treatment, if we would save our patient, for delay in either is almost certain death. I wish to be understood as speaking of diphtheria proper (not homœopathic diphtheria, *i. e.*, simple ulcerated tonsillitis, which, in nearly, if not all, instances will get well in a few days without treatment of any kind). A few points concerning the treatment:—

My experience and observation extend over a period of eight years. I have seen the disease in its various stages and types. If you begin treatment within twelve hours from the onset of the disease (membrane formation) the patient with proper treatment will recover.

If you begin treatment twelve to eighteen hours from the onset of the disease you may expect to lose a patient occasionally.

If you begin treatment from eighteen to twenty hours after the onset of the disease you may expect many fatal cases.

The disease is one which usually runs a rapid course; the patient dying in from four to six days, mostly. I have seen cases perish in forty-eight hours where no treatment had been given.

This being the case, it is evident that to accomplish anything satisfactory the treatment must be prompt and thorough; the patient must have the same attention night and day, until you have the disease thoroughly under control.

I rely upon the following plan of treatment (having tried many other modes and abandoned them because not reliable): pure air, of proper temperature; quinine and iron, in form of elixir, in tablespoonful doses every two hours for an adult; proper nourishment—extract of beef, milk, eggs, good port or sherry wine.

Locally, internally, tincture of iron with glycerine, in the proportion of two parts of the former to one of the latter, and this mixture saturated with chlorate of potass.; this should be thoroughly and carefully applied, every six hours, to the fauces, tonsils, etc., by the physician, and never entrusted to inexperienced persons. A gargle consisting of one part of the above mixture and three parts of water should be used every two or three honrs. Small pieces of ice may also be allowed to dissolve in the mouth to good advantage when not annoying to the patient.

Locally, externally, nothing, except where there is swelling of the lymphatics; then the application of lin. ammon.

If the above plan of treatment is faithfully carried out I know that the mortality of this much dreaded disease will be very much lessened. A single example of the importance of early and thorough treatment.

No one of experience will probably deny, all things being equal, that children will perish from the disease more frequently than adults.

A family of ten persons, father, mother, four children between the ages of six and twelve years, and four (three sons and one daughter), between the ages of seventeen and twenty-five, all but the father contracted the disease. I was called in consultation when all had contracted the disease. The mother, adult daughter and two adult sons had already died, and one other son

was in a dying condition (all happening within a period of two weeks); the children, four in number, under twelve, though having the same type of disease to contend with, all recovered. The treatment adopted was the same for children and adults, and in the main such as here suggested. Why did the adults die and the children recover? Because the adults refused to have any treatment until the disease had far advanced, and the children were forced to treatment early.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINIC BY GEORGE H. FOX, M.D.,

Professor of Dermatology.

Pediculi.

Gentlemen:—To-day we will continue the subject of animal parasites which cause disturbance of the skin in man. There are three kinds of the pediculus: the pediculus capitis, or head-louse, the pediculus pubis, or crab-louse, and the pediculus vestimenti, clothes or body-louse. These pediculi produce three forms of phthiriasis: phthiriasis capitis, phthiriasis pubis, and phthiriasis corporis.

These pediculi resemble each other in their anatomical structure and in their general appearance, to a very great extent, and it is singular there should be such a contrast between the affections which the three species cause. Why it is that one louse should inhabit only the scalp or hairy portion of the head, why another should infest all the hairy portions of the body except the scalp, and why still another should harbor in the clothing entirely, being found only in the seams and folds of the garments, and never among the hairs of any portion of the body, is a question very difficult indeed, and impossible, I may say, to answer.

Now, the treatment of any of these forms of phthiriasis is merely local. The old idea of the disease being a specific dyscrasia was long ago exploded, but still there are very many among the lower classes who believe now that the pediculi are bred by the disease; in other words, that they are the effect rather than the cause of the disease. You will find this idea firmly rooted in the minds of many of the less intelligent patients, so that it will often be almost impossible to get them to carry out the local measures prescribed until you talk with them for some time, persuading them that their blood is not disordered, calling for internal treatment, but that the trouble is caused altogether by the lice upon the skin or in the clothing, and that local remedies, if efficiently applied, will be sufficient to effect a cure.

It is convenient to discuss these three forms of phthiriasis separately. Take first the phthiriasis capitis, which is very common. It is an affection which occurs very largely among the children of the poor, but from them is very frequently transferred, either directly or indirectly, to the children of the rich. Adults, of course, are not exempt from it, and women, on accouut of their long hair, are more likely to get it than men.

When the insects get into the hair they proceed to deposit their ova upon the hair of various portions of the scalp, usually in the temporal region, and usually near the scalp itself, from which they draw their sustenance. These nits are little pyriform bodies adherent to the hair, the small extremity always pointing toward the scalp. Three, four or a dozen or more may be deposited upon a single hair, and always near the scalp; therefore, when you look at any case of phthiriasis capitis and find that these nits are removed some distance from the scalp, you may know at once that the disease has existed for some time, the gradual growth of the hair accounting for the distance of the nits from the scalp.

These nits hatch out in a very few days, and give rise to a certain amount of itching, which generally leads to a diagnosis of the trouble, either by the patient or by the friends, the mother, or the nurse. If the patient be a child, they will notice that the child is scratching the head more than usual, and on examination they will find one or more of these nits upon the hair, usually, as said, upon the hair of the temporal region. Sometimes it is rather difficult to say, unless there be rather a strong light, whether a little excrescence, one or more, upon a hair are really ova, or whether they are little shreds of epithelium, which is sometimes adherent. If the hair, however, is removed and examined with a strong light, this peculiar pyriform shape of the nit will be at once apparent, and the diagnosis can be readily made. When the disease has existed for a long time, in children who have been neglected, or in adults, as I have often seen it, you will find that the hair appears as though it had been covered with some rough or coarse white powder, each individual film being studded with these ova.

As regards the treatment, I have said that the treatment of all of the forms of phthiriasis should consist simply in the application of local remedies. At the same time, I must say that there are some writers who believe that there is a certain predisposition, or a certain condition of the skin which predisposes, to attacks of the pediculi, and I must admit that there are very many children who seem to catch lice upon the slightest provocation. In a family of a number of children, when exposed, one or two will get lice and others will escape; but this I think must be due to the readiness on the part of some of the children to associate with every description of playmates, whereas the others hold themselves more aloof. Certain persons troubled with this affection care nothing about cleanliness, and only resort to it when their itching becomes so intense that life is a burden to them. Now, if any person in perfect health should subject themselves to the same causes as these persons do, we would undoubtedly find that they would be just as lousy. In other words, the condition of the patient's health has nothing whatever to do with the existence and the persistence of these pediculi. I must say, however, that many writers have recorded cases of phthiriasis where the disease

could not be cured by local treatment until the patient had been given cod-liver oil or some internal remedy, which has. they say, seemed to change the condition of the system, and along with it the condition of the skin, so that the insect could be destroyed. Notably among these, is Hebra. This, however, I think is a mistake. McCall Anderson, a most excellent writer on dermatology, I know, speaks of some cases of phthiriasis corporis, or body lice, occurring in broken down subjects, where a cure could be greatly accelerated by the administration of cod-liver oil, etc. So far as my experience goes, the ordinary local treatment will cure phthiriasis long before cod-liver oil, etc., would begin to have any effect whatever.

Now we will suppose that we have one or two cases of phthiriasis capitis to treat. We will find that the treatment depends greatly upon the social condition of the patient, and largely upon the chronicity of the disease and the number of the pediculi and ova present. In private practice the disease is generally discovered soon after the pediculi have found lodgment upon the scalp, and when there is a very slight amount of irritation. It will be difficult to tell, in some cases, whether the child is really suffering from the pediculi, for you will often be unable to find the insect until you have examined one or two hairs in a very strong light. Having found one or two nits, however, the diagnosis is made.

Now, in such a case, what is the best plan to pursue? I have had occasion to treat the disease in my own family. I do not know but what I brought the lice home myself, for I have brought pediculi home upon my clothing, from the dispensary, repeatedly, and the treatment I have adopted in private practice has been to rub in a very little of the white precipitate ointment. In the milder cases that rarely fails to effect a cure in a few days. A number of remedies have been recommended, but as I have found the white precipitate ointment, full strength, rubbed, not in the scalp, but throughout the hair, will effect a cure in a few days, it is not necessary to consume time in naming the various remedies which may have been proposed. But there may be some objection to using this ointment on the hair, especially because of matting the hair together. If you want a more elegant preparation, use a one per cent. solution of corrosive sublimate, either in alcohol, water, or Cologne water. Another prescription may be used, as follows:—

℞.	Hydrarg. chlor. corros.,	1	
	Thymol,	4	
	Alcohol,	100	
	Ol. amygdal. ama.,	q. s.	M.

The mercurial solution alone is sufficient to kill the pediculi, and in the milder cases there is no danger from the absorption of the drug. If there has been very much laceration of the scalp, from the scratching, or if there are any spots of eczema present, of course it would be unsafe to use a strong solution of corrosive sublimate, or, in fact, to use corrosive sublimate at all. The alcohol is also a parasiticide, and gives a peculiar odor to this lotion which is not pleasant to the pediculi, and the thymol or the Cologne water, if you wish to use it, tends to loosen the ova from the hairs. Very often a solution is used which kills the pediculi but does not kill the ova, in which case, in a few days, a fresh colony of the insects is present. The oil of bitter almonds added to the mixture counteracts the peculiar odor of the alcohol and gives a more pleasant fragrance. Where you wish the effect of corrosive sublimate upon the skin you will find this a very pleasant lotion to use. As I say, it can be used with impunity provided it is applied to the unbroken epidermis. If you use it upon the face or scalp of a child suffering from moist eczema, I would not undertake to be responsible for the consequences. I have written this prescription in the decimal system. I do not care whether you use grams or drachms, or what not, but the decimal system is as much superior to the system in vogue as the decimal system of money is superior to the sovereigns, crowns, etc., of the English. I am in favor of changing the system, not for the sake of making a change, but simply because the decimal is much more convenient. A good plan would, I think, be to give up using grains, scruples, ounces, etc., and use simply the drachm as a unit, instead of the gram, and make your prescription a decimal one. No matter, in fact, what unit you use, as a hundred drachms, fifty drachms, etc, by making every prescription amount to one or more hundred parts, or some decimal portion of one hundred, you can see at a glance the percentage of each ingredient.

The pediculus pubis looks like a crab, and consequently we have the common name, crab-louse. The same treatment which will remove the pediculi from the hair will also remove the pediculis pubis. Ordinarily we find the phthiriasis pubis affecting simply the pubic region; but you must bear in mind, strange as it may seem, that you will sometimes find this pediculus in the axilla, sometimes in the eyebrow and upon the eyelashes; I believe some cases have been reported in which it was found on the scalp, but if it be so it is extremely rare. I have never seen such a case myself.

The ointment which is ordinarily used in the treatment is the blue ointment, or ordinary mercurial ointment of the Pharmacopœia. There is no doubt about its being an efficient remedy, but the majority of patients will use so much of it, and rub it in so hard, that about one-third of the cases, at least in dispensary practice, will be found next day with a severe eczema of the scrotum, etc. That is too much of a good thing. The ointment of ammoniated mercury is far more cleanly. Or you can use the lotion of corrosive sublimate which I have just given you.

Phthiriasis corporis, or pediculi which infest the clothing, look very much like the pediculi which infest the scalp, but larger. Although you may find them on the skin after the clothes have been removed, you must bear in mind that these insects do not infest the skin, but live in the seams and folds of the clothing, and merely come upon the skin to pasture, as it were, to insert their little probes and draw the blood from the superficial vessels.

Now, the eruption which the pediculi in the clothing make is a peculiar one, and is due wholly to the scratch mark. If a person were paralyzed, or confined with a strait jacket, you

would not find the peculiar eruption in phthiriasis corporis, nor would you find it, for that matter, in scabies. It has been repeatedly noticed in insane asylums and hospitals, where persons have contracted scabies and could not use their nails in scratching, that the ordinary eruption was not present.

We make the diagnosis of this affection in two ways: First, by finding the lice upon the clothing, which is not difficult where they are numerous; and second, by noting the peculiar location of the eruption, which consists only in scratch marks. There is one peculiarity about these scratch marks of phthiriasis which does not occur in scabies and other affections of the skin, and that is that they are very long and very little. In other words, there is no other affection of the skin in which the pruritus is so intense as in the affection spoken of. In scabies, in urticaria, and other affections of the skin you will often find the skin torn and bleeding, but you will never find the patient taking four or five nails of one hand and drawing them across the skin and leaving bleeding marks, as you find in phthiriasis corporis. In scabies the eruption depends largely upon the character of the clothing; so in phthiriasis we find the scratch mark, in the first place, most abundant across the shoulders, and from this fact alone the diagnosis may often be made. In the second place, we find a ring or girdle of excoriations around the loins, upon the hips and outer surface of the thighs. Why is this? Simply because across the shoulders we have the shirt occurring in folds, and these folds give harbor to the pediculi. Around the waist, where the clothes are tied tight, being brought closely in apposition with the skin, as is often the case with workingmen, we find the pediculi; and, consequently, intense itching will occur in these regions, and, of course, the patient will scratch where he itches most. I remember a very peculiar case at the New York Dispensary some years ago, where the patient had stripes of excoriations upon the outer side of the thighs and legs, and also upon the inner side of the thigh not quite so marked. On the anterior and posterior aspect of the thigh he was almost entirely free from the eruption. Now, this peculiarity struck my view at once, and I was at a loss to know what caused it, until one of the students who was present suggested looking at the patient's pants. It was simply because the seams of the pants were almost white with the ova of the pediculus, and, of course, the irritation had occurred just in the line of the seams.

If you take all the clothing of the patient, not only those which he is wearing at present, but those which he has been wearing, and throw them away, and put him into a clean bed in a hospital, the disease itself is cured. It may take several weeks to cure the secondary eczema which may be present, or even perfectly to heal the excoriations of the skin, but the cause of the trouble is removed as soon as you get rid of the infected clothing, and that is the first thing to do, except, as I have said before, to convince the patient that he has lice. Many will deny it. In private practice it often requires a great deal of delicate tact to tell the patient that the trouble is not due to the blood, but to infection of the clothing by lice. It may be in persons who are very nice about their toilet, the last persons in the world that you would suspect giving harbor to the pediculi; but such cases do occur. I have had them a number of times. It is very easy to get pediculi upon the clothing in public practice; it is almost impossible, however, to contract scabies. I have handled the hands of scabies patients by the half hour or hour, and never had any fear whatever of contracting the disease. At the dispensary, and at clinics, and in the street cars the pediculi are very apt to move from the clothes of one affected to your own.

Now, in those cases where there are only one or two pediculi to be found, or perhaps, none at all, but merely the peculiar marks upon the skin which you recognize as being caused by this affection, the only thing to do is to explain to the patient just what the cause of it is, and advise that the underclothing, and the outer as well as the under, if he wear woolen clothing, be baked in a very hot oven. They can be rolled up in a newspaper and put upon a board and baked in an oven where the temperature is at least 150 or 200 degrees, or more. This will kill the insect and the ova as well. In dispensary practice, where we find not only pediculi present in large number, but this lacerated or excoriated condition of the skin, we not only advise the patient to bake his clothing or buy new, but we have to do something to remove the effects of the skin scratching. For this I have generally advised, for public practice, a tolerably strong lotion of carbolic acid, perhaps thirty grains to the ounce. An infusion of larkspur seed may be used, or ointment. The ointment is largely used in Germany and England, and to a slight extent in this country. Another remedy may be used in connection with phthiriasis capitis, to lessen the itching of the skin and prevent the pediculi from getting access to the body, that is, petroleum.

In severe and neglected cases of pediculus capitis in children, it is a good plan to advise the use of petroleum, a remedy which they usually have in the house, and saves the expense of getting the bichloride solution. I tell the patient usually to anoint the head thoroughly with oil at night, not to rub it in near the gas jet or lamp, through fear the patient may take fire. If there is very much eczema present the oil will cause considerable smarting, and it might be well, in some cases where there is considerable eczema, to treat first before we begin to remove the pediculi, or simply to use the white precipitate ointment in the hair. But if there is not much eczema of the scalp, we can tell the patient to rub the oil thoroughly into the hair and put on an oiled silk cap, or other suitable cap, and sleep in it over night. In the morning the scalp can be washed thoroughly with soap and water, and the disease will be partly cured. It is necessary, however, in some cases, to repeat this night after night, for three or four days. There is, perhaps, no more efficacious remedy than the petroleum thus used. In pediculus corporis, you can tell the patient to do the same thing, keep the skin greased with the oil; the odor, it seems, prevents pediculi from going to the skin. Where they go to may be a mystery, but soon they will be found in much fewer numbers in the clothing.

Periscope.

Excision of Pylorus, for Cancer.

In the *British Medical Journal*, Dr. F. A. Southam reports the following instructive case, which, from its great practical value, deserves a full notice:—

Richard S., aged 43, gas-fitter, was admitted to the Manchester Royal Infirmary, under the care of Dr. Ross, on March 13th, 1882, suffering from symptoms of pyloric obstruction, which had first shown themselves about four months previously. The patient, who was much emaciated and was rapidly losing flesh, was, at the time of admission, unable to retain any solid food, as sickness always came on about an hour after a meal, the vomited matter being at times mixed with a little blood. Fluids, however, if taken in small quantities, were retained by the stomach. The bowels were very constipated, only acting about once a week, and the motions were dark and tarry. The patient complained of considerable pain in the region of the stomach, always increased after taking solid food. On examination of the abdomen, as the patient lay on his back, a hard, well defined, somewhat nodular mass, apparently about the size of an orange, could be distinctly felt close to and a little to the right of the umbilicus, corresponding in situation with the pyloric extremity of the stomach. The tumor, which was freely movable, shifted its position with the respiratory movements, and also with the position of the patient, falling to the right or left of the middle line, according as he turned to either side. On making pressure over it considerable pain was felt. No dilatation of the stomach could be detected, and the condition of the other viscera appeared to be perfectly normal. From the history and the symptoms which were present, Dr. Ross had little difficulty in diagnosing the case as one of cancer of the stomach; and as, from the mobility of the mass and the fact that it was perfectly free from any connection with the abdominal walls and adjacent organs, the disease appeared to be limited to the pylorus, the case was considered a suitable one for operative interference.

As he was very rapidly losing ground, growing daily more emaciated, preparations were made for performing the operation on April 5th. In order that the bowels might be thoroughly cleared out, simple enemata were administered the two preceding evenings, and brought away a large quantity of dark-colored feculent matter. No food was given by the mouth for twelve hours previously.

The operation was performed at 10.30 A.M. on April 5th, according to the method adopted by Professors Billroth and Dr. Wolfler (*Clinical Surgery*, by Dr. Billroth; New Sydenham Society, p. 493), with antiseptic precautions. To guard, as far as possible, against the effects of shock, the patient's extremities were carefully wrapped up in blankets, and hot bottles were kept applied to the soles of the feet and sides of the thighs and legs. As soon as the patient was fully anæsthetized, a siphon stomach-pump was passed, and the interior of the stomach was several times thoroughly washed out with tepid water. The necessity of this measure was proved by the fact that a large quantity of dark-colored, grumous matter was brought away, which otherwise would probably have escaped into the peritoneal cavity when the viscus was opened.

The operation itself may be divided into five stages.

1. *Exposure of the Tumor.*—This was effected by a transverse incision, nearly six inches in length, carried across the abdomen about two inches above the umbilicus, and dividing the recti muscles. All bleeding having been arrested, the peritoneum was divided to the same extent, and the growth was then freely exposed to view. (Fig. 1.) It was found, as was expected, limited to the pyloric extremity and adjacent portion of the walls of the stomach, being perfectly free and movable, except at its posterior aspect, where there were a few slight adhesions to some enlarged lymphatic glands which lay close to the head of the pancreas. These having been readily broken down with the finger, the pylorus and diseased mass were drawn forward as far as possible, so as partially to protrude through the abdominal incision.

2. *Isolation of the Pylorus and Tumor from the Large and Small Omenta.*—The tumor having been drawn forward as far as its connections allowed, the great omentum was first separated from the greater curvature of the stomach, by taking it up in three portions, between three double catgut ligatures, and then dividing it between each pair of ligatures with scissors. The small omentum was then separated from the lesser curvature in a similar manner, five double ligatures being used. In this way, the pylorus and diseased mass were completely freed from their connections with both omenta, without any hemorrhage; and being quite isolated, the tumor could now be drawn forward through the external wound, so as to lie altogether outside the abdominal cavity. This having been done, a large, flat sponge was laid beneath the stomach, so as to cover in the greater portion of the wound, and in this way prevent any prolapse of the intestines, and the escape of any blood, or of the contents of the stomach and bowel, after their division, into the interior of the abdomen. By this means, the remainder of the operation was performed altogether outside the peritoneal cavity.

3. *Excision of the Pylorus and Tumor.*—This was effected in the following manner. A thick silk ligature was tied around the duodenum, about an inch and a half from the pylorus, so as to prevent any extravasation of its contents from taking place after its division, and also to guard against its slipping away after its separation from the stomach. The duodenum was then divided with a pair of scissors between the ligature and the pylorus, about half an inch from the tumor and well clear of the disease. The distal por-

tion, with the ligature round it, was then drawn over to the right side, while the stomach itself was divided. This was again effected with scissors, the division being commenced about the centre of the lesser curvature, and carried obliquely across toward the great curvature, in a line slightly convex toward the left side. (Fig. 1.) In this way, the pylorus, along with the tumor, was completely removed. The contents of the stomach, which was almost empty, were soaked up with a sponge; and its interior was carefully washed out with a weak carbolic lotion. Contrary to what one would have expected, the division of the stomach was attended by very little hemorrhage, only two small vessels on its anterior wall requiring torsion—the result, no doubt, of the powerful contraction of its muscular coat. Nor was the division of the bowel accompanied by any bleeding, the pressure of the ligature round it probably preventing any hemorrhage. After the removal of the tumor, a mass of enlarged glands surrounding the head of the pancreas was freely exposed to view. Some

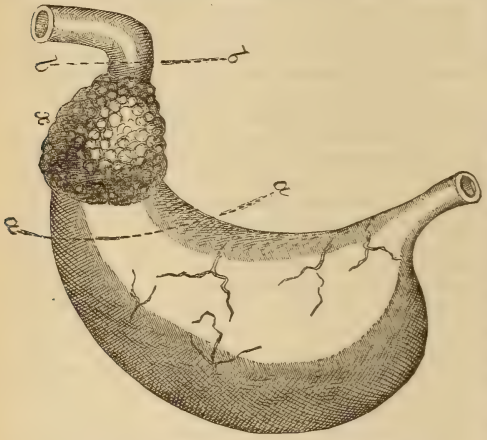

Fig. 1.—Shows position of growth, *x*, and lines of division, *a a*, of stomach, *b b*, of duodenum.

of these were removed; but, as they were found to involve the biliary and pancreatic ducts, it was thought advisable not to interfere too much with them, for fear of injuring those important structures.

4. *Closure of the Opening in the Stomach, and the Insertion of the Duodenum into it.*—The opening in the stomach was next partially closed by twenty-one silk sutures, commencing from above downward, *i. e.*, beginning at the lesser curvature, a small opening being left at the great curvature for the insertion of the duodenum. The silk ligature was then removed from around the duodenum, and the orifice of the bowel was attached to the opening which had been left in the stomach at its greater curvature by means of nineteen silk sutures (Fig. 2). The sutures having been cut short and the sponge

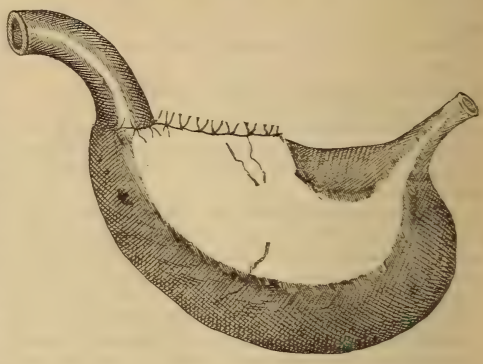

Fig. 2.—Shows condition of part after removal, of growth and attachment of duodenum to stomach.

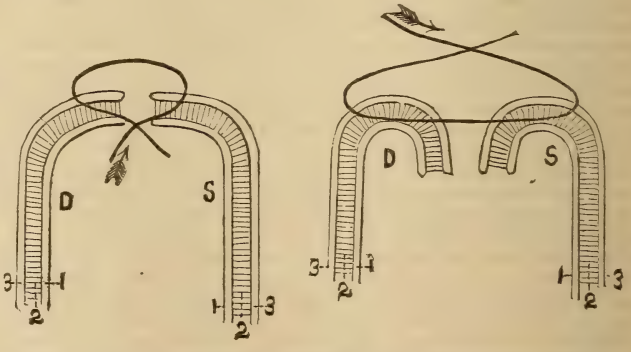
removed, the stomach was returned into the cavity of the abdomen; all bleeding points were arrested, and the peritoneal cavity was then carefully sponged out.

In the insertion of the sutures two different methods were adopted, with the object in each case of bringing into contact with one another a considerable margin of the opposed serous surfaces of both stomach and intestine. In uniting the posterior walls of the duodenum and stomach, the sutures were inserted from within (according to the plan recommended by Billroth), the needle being introduced between the mucous and muscular coats of the stomach (s), and then made to pierce both muscular and serous coats; it was then passed in the reverse direction through the coats of the duodenum (d), viz., first through the serous and muscular coats, and then between the muscular and mucous coats. In this way, on drawing tight and tying the sutures, a considerable margin of the serous coats were brought into contact with each other, and the margins of the mucous membrane at the same time fell into apposition, covering over the knot of the sutures, which in this way was left



Figs. 3 and 4.—*s*, Stomach, *d*, Duodenum. 1, Mucous Membrane, 2, Muscular Coat, 3, Serous Coat. The dark line with the arrow shows the direction in which the sutures were passed.

between the mucous and muscular coats at the point of junction of the stomach and bowel (Fig. 3). In uniting the anterior walls of the duodenum (D) and stomach (S), and also the two cut surfaces of the stomach itself, a somewhat different method was adopted, the sutures being entered from without. The opposed margins of the cut surfaces were slightly inverted (Fig. 4), so as to bring the serous surfaces well into contact with each other; the needle was then introduced from without, so as to pierce in succession the serous, muscular, and serous coats of each opposed surface. After tying the sutures, the knot lay altogether external to the stomach and bowel, and at the same time their serous surfaces were brought well into apposition with each other.*

5. *Closure of the External Wound.*—This was effected in the ordinary way, by means of nine silver wire and sixteen silk sutures, passed so as to include the peritoneum. Considerable difficulty was, however, experienced in bringing the margins of the wound into contact with one another, owing, no doubt, to the contraction of the divided recti muscles, and I think, therefore, that on this account a longitudinal incision through the abdominal walls would be preferable to the transverse one as recommended by Billroth. The wound was then dressed antiseptically, and as I regretted afterward, no drainage tubes were employed. The patient was then removed to bed, the operation having lasted exactly one hour and a half. No sickness occurred during its performance, and a very fair pulse was maintained throughout.

Nutrient enemata and subcutaneous injections of morphia were administered every four hours. At 1 P.M. (one hour after the conclusion of the operation), pulse 88, full and strong; temperature 97.6°. The patient was sleeping quietly. There was no sickness. The extremities of the skin were warm. At 5 P.M., temperature 98.4°; pulse 120. He was quite conscious, and complained of thirst and pain about the abdomen. He appeared to have quite rallied from the shock of the operation. At 10.30 P.M. temperature 99 8°; pulse 138, soft but regular. The patient was sleeping quietly; the extremities and surfaces of the body were warm. At 12.30 A.M. temperature 102°. He had been sleeping quietly for some hours. There had been no sickness since the operation. Shortly after this, the night nurse noticed a change come over the patient, and death took place very suddenly, about 1.30 A.M., nearly fourteen hours after the conclusion of the operation.

A Post mortem Examination was made the following day. The internal organs were all perfectly healthy. No secondary deposits were present, except in the mass of glands to which reference has been made as surrounding the head of the pancreas. There was slight injection of the parts in the neighborhood of the stomach, and a quantity of bloody serous fluid was found in the peritoneal cavity. As regards the parts which had been divided, a certain amount of union had already taken place, a thin layer of lymph having been poured out, as the result of which there was slight adhesion between the opposed serous surfaces of the stomach itself, and also between those of the stomach and the duodenum. The whole of the growth had been removed, the portion of the stomach which had been left, and the bowel itself, beyond the point at which it had been divided, being found perfectly free from any trace of the disease. *Microscopic Examination* of the parts removed at the time of the operation (*i. e.* the pylorus, and about one-third of the anterior and posterior walls of the pyloric extremity of the stomach) showed that the growth consisted of scirrhous cancer. The pylorus was entirely surrounded by the growth, its opening being so contracted as barely to admit the tip of the finger. The pyloric extremity of the stomach was also involved, more especially its anterior wall, the mucous surface of which was studded with a number of distinct nodules. The duodenum was similarly affected for about half an inch; beyond this point the walls of the bowel were perfectly healthy.

Remarks.—With regard to the cause of death, I suppose it must be referred to what is generally included under the term shock; but inasmuch as reaction had become fairly established, the patient appearing to have quite rallied from the effects of the operation, and since death was preceded by a sudden and rapid rise of temperature, may not the fatal result in this, as in many other cases of abdominal surgery, be possibly due to what has recently been described as "septic collapse," or "septic intoxication," that is to say, pure chemical poisoning, from the sudden absorption of a large quantity of poisonous material by the extensive absorbing surface of the peritoneum?

From the nature of the operation, involving as it does the division of the stomach and intestine, it is not possible to keep the parts involved perfectly aseptic; and even if it were, from the physiological law of osmosis, it is not improbable that the fluid which is poured out into the peritoneal cavity soon becomes infected by the formed ferments which are present in the alimentary canal, and which may make their way into it through the walls of the intestine. Hence a septic peritonitis is liable to be set up, which may destroy life in a few hours, from a very acute form of blood-poisoning.

The rapid rise of temperature just before death, the sudden collapse after reaction had become established, and the presence of a quantity of sanious fluid in the cavity of the peritoneum are, I think, arguments in favor of the correctness of this theory.

For these reasons I should, if called upon to perform the operation again, be disposed to introduce one or more drainage tubes into the abdominal cavity through the external wound, or through a counter-opening made in the loin, and attempt to draw off from time to time, by means of a syringe, any inflammatory effusion which might collect.

* The second row of sutures, passed so as to include only the cut margins of the mucous membrane (as recommended by Billroth), were not employed, as they seemed unnecessary, the two mucous surfaces falling accurately into apposition with one another without. Silk sutures were used in preference to catgut, as the latter, if acted upon by the gastric juice, might have softened and given way before union could have taken place.

Gunshot Wound of Brain.

The *Lancet* records the following wonderful case: On June 14th, a young gentleman, nineteen years of age, was found lying on the ground near Torquay, with a pistol wound in the head. He was taken to the Torbay Hospital, and from information kindly afforded us we are able to state the nature of his injuries. There was a wound in the right temporal region, perforating the skull and the dura mater, and permitting the escape of brain matter. There was also extensive comminution of bone in the left parietal region, from internal impact of the bullet, but here there was no external wound. When found the lad was conscious, and all symptoms of shock and concussion soon passed off. On the fifth day left facial and lingual paralysis was noticed; no other paralysis or any alteration in sensibility has since developed itself. The temperature has been within the normal range, except a single rise to 102°, on the third day, and the pulse has been regular throughout, only ranging from 60 to 68. The lad eats and drinks well, and his intellectual faculties are good. The wound is granulating, and up to the 5th inst. no fresh symptom had arisen. The bullet is conical, one-third of an inch in diameter, and it remains lodged in the cranium. According to Dr. Ferrier's experiments, the injury to the convolutions is localized in and near the ascending and middle frontal convolutions. This case has been mentioned in the lay press, where it has been erroneously stated that a considerable part of the frontal bone with brain matter attached had been shot away, and great surprise has been expressed at the boy's living after such an injury. The case is very interesting and remarkable, but by no means unique. Larrey drew attention to the fact that bullets may remain encysted in the brain for years without producing symptoms. In the surgical history of the American war many cases of recovery—some partial, some complete—after perforation of the brain by bullets, and after comminuted fractures with destruction of brain matter, are recorded. In the Franco-German war other similar experiences were met with, and Dr. Gilbert Smith has related the case of a man who recovered from a sabre-cut received in the first Carlist war. The wound was followed by hernia of the brain, and the man was seen alive and well several years afterwards, with a large cavity within the skull, and an opening in the bone. His faculties were unimpaired, as shown by the fact that he was engaged in his business of a photographer. It is a well known fact that injuries to the anterior part of the brain are less serious than similar injuries inflicted further back.

—The culture of cinchona in India began in the year 1858; especially cinchona succirubra, as also cinchona calisaya, were planted, while cinchona officinalis did not seem to prosper so well in that climate. There are now in India 4,677,720 China trees; 4,034,535 are cinchona rubra; 412,695 cinchona calisaya; 199,893 a variety of the latter, and 30,592 other kinds. Last year 9296 pounds cortex were brought into commerce.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the First Quarterly Report of the Eye and Ear Dispensary of Starling Medical College, of Columbus, Ohio.

——West Virginia has never aspired to a leading position among the States of the Union, yet the Report of the Transactions of its Medical Society, which lies before us, affords ample evidence that this good State has thoroughly held its own from a professional point of view. A complete index makes easily accessible all the really good material in this volume.

——The Report of the Transactions of the Medical and Chirurgical Faculty of Maryland, at its eighty-fourth annual session, contains very much of interest. The Report of the Section on Sanitary Science contains an account of the yellow fever epidemic of 1855, the ravages of which did so much to arouse the slumbering people to a sense of their danger, which resulted in a Convention in Philadelphia in 1857, Baltimore, 1858, New York, 1859, and Boston, 1860, to discuss anew the subject of quarantine and sanitary regulations. Dr. Van Bibber contributes a valuable article on the "Drinking Waters of Maryland," illustrated by a map. Anatomy, surgery, practice of medicine, obstetrics, physiology, all the branches of our science, indeed, are represented in these Transactions, which are well worthy of careful reading.

——Dr. Charles A. Oliver has recently been making some experiments on the comparative action of sulphate of daturia and of sulphate of hyoscyamia upon the iris and ciliary muscle, which we receive as a reprint from the *American Journal of Medical Sciences*, July, 1882. Hyoscyamia will sometimes produce such grave constitutional disturbance that we must be cautious in its use. The astringent and irritant action of the two drugs upon the conjunctiva may be avoided by the use of a neutral salt. The long-continued dilatation of the pupil, and the slow return of the ciliary power occasioned by the amounts given of both the drugs, render them absolutely useless when we desire accurate ophthalmoscopic examination in cases dependent upon their use. Such are a few of the results of these observations, for an intelligent comprehension of which it would be necessary to peruse the pamphlet.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE APPROPRIATION FOR THE PREVENTION OF EPIDEMICS.

There has been a good deal of hard feeling about that $100,000 appropriation for the prevention of epidemics. The National Board of Health expected it and did not get it, and in consequence have had to cut down their organization and suspend their *Bulletin*.

The clause of the Appropriation bill ran thus:—

"The President of the United States is hereby authorized, in case of a threatened or actual epidemic, to use a sum not exceeding one hundred thousand dollars, out of any money in the Treasury not otherwise appropriated, in aid of State and local boards, or otherwise, in his discretion, in preventing and suppressing the spread of the same."

After considering the matter, the President decided to employ this contingent appropriation through the agency of the Treasury Department, and that, in case of a threatened or actual epidemic, immediate action should be taken, upon application from the Governor of a State addressed to the Secretary of the Treasury.

This meant that the spending of the money is to be through the United States Marine Hospital Service, a most excellent and efficient branch of our civil medical staff, of which, as most readers know, DR. JOHN B. HAMILTON is Surgeon General.

He has issued a circular to the officers of the corps, calling their attention to the following paragraph of its regulations:—

"Medical Officers and Acting Assistant Surgeons are, under the direction of the Supervising Surgeon General, required to observe and to aid in executing the quarantines and other restraints established by the health laws of any State, and to report forthwith to the said Surgeon General any important event or fact that may come to their knowledge bearing upon the importation, outbreak, or spread of cholera, yellow fever, smallpox, typhus, or other epidemic disease, at or near their respective stations."

This is all very well, and we do not doubt but that the interests of the public will be well cared for, and the money honestly and judiciously expended by the Marine Hospital Corps. It has proved itself a most useful and intelligent body, and a hundred thousand for it to expend is little enough.

But there were peculiar fields of investigation and research, of the very highest value to science and health, to the country and to humanity, in which the National Board of Health was working, which must now lie fallow. Its *Bulletin* was indispensable to the statistician, and its authority daily growing.

That this Congress prostituted $19,000,000 of the people's money to the iniquitous and fraudulent River and Harbor Improvement Steal, and not one cent to the National Board of Health, are two facts that should consign every member who voted for that measure to political and personal ignominy for the rest of his life. Such a body of legislators are as destructive of the moral as they are negligent of the physical health of the nation. The heavily taxed people are robbed of millions, and the pittance asked to guard against pestilence is refused. Not a single representative who aided in these two actions will ever have a second term, if his constituents are honorable and intelligent people.

It is the solemn duty of the voters of this country to demonstrate, by unmistakable action, to their recreant representatives that they heartily disapprove of their dishonest and foolish legislation.

SANITARY INSPECTORS.

The story has been told of the physician who met an undertaker on a warm day, in the early summer, before a street stand, on which was exposed for sale a variegated assortment of green and unripe fruit. They stopped, shook hands, glanced toward the stand, smiled, and with a look of gratification walked on, arm in arm, delighted with the prospects of active business which this view afforded them. We were forcibly reminded of this story a few days ago, when, passing one of these stands on a crowded thoroughfare, we noticed that the enterprising proprietor had selected from his stock an assortment of *rotten* bananas, peaches and apples, which he had placed on a board by themselves and labeled for sale at a price much below that asked for the ripe and wholesome fruit. Our first feeling was one of anger, which soon gave way to reflection, as we realized that this poor, ignorant man was probably unaware of the full extent of the injury he was tempting his fellow creatures to do themselves. We thought how good an act could be performed by some philanthropist whose purse is always open to benefit mankind, by purchasing this rotten and poisonous fruit from the vender, who would thereby be protected from a loss which had been caused through no fault of his; and taking it to the next corner, throw it all into the common sewer, thereby saving many of his fellow beings from the dangerous sufferings which the consumption of this rotten mass would almost inevitably produce, and the cheapness of which is a temptation well nigh irresistible to the ignorant and poorer classes of our population.

But philanthropists (noble men as they are) do not, as a rule, give much attention to these seemingly trivial matters to the uninitiated. Sitting in their offices they dispense their wealth with a lavish hand for the erection of hospitals and educational institutions, but these little matters they neglect, because, we believe, their attention has not been sufficiently called to them. We believe that a system of so-called sanitary inspection does exist in our city, and that some one has the authority to prohibit the sale of unwholesome fruit, but if such a law does exist, we must, perforce, from the unerring evidence of our senses, regard it as a dead letter; its observance, if it ever was observed, is a matter of history, dating so far back that no man's memory can recall it. We should awaken from this state of lethargy, of dangerous inactivity, and our philanthropists, who have time, means, and inclination, are the ones to inaugurate such a reform. We want a corps of sanitary inspectors, whose time shall be devoted to honestly inspecting the sanitary condition of the districts under their charge, and who shall be given the authority to order the removal or abatement of any nuisance that may exist and to enforce their orders.

In the instance of the rotten fruit referred to, they should be authorized to empty it into the common sewer. The tobacco merchant cannot sell ruined tobacco, because his customers are too sharp to buy it from him; if, then, the customers of the street fruit vender are too ignorant to discriminate between what they ought and what they ought not to eat, they should be protected by those wiser than themselves. This power to prevent the sale of, should apply equally to all articles commonly used for food. These inspectors should regularly visit and carefully inspect all provision shops and market houses in their districts, and condemn that which is unfit for use, and see that their condemnation is not disregarded. It will not do to leave this sanitary reform to professional politicians, for two reasons.

1st. They have not the requisite knowledge of sanitary science to enable them to efficiently carry out the reform.

2d. Professional politicians are, as a class, notoriously lazy, except at electioneering times, when they are full of activity, whisky and promises, the latter of which are forgotten as soon as the election is over. They would neglect such work as would be necessary to carry out this reform, because by so doing they would make enemies and lose votes in their districts.

This duty should be relegated to intelligent physicians who have made a special study of the science of hygiene. In our last issue we recommended the establishment of a corps of police surgeons. By combining the two duties, by making an intel-

ligent physician, who is also a sanitarian, the police surgeon and sanitary inspector of his district, and paying him a liberal salary, he could devote all his time to his dual duties, and they would both be efficiently carried out. There are plenty of physicians to fill these positions satisfactorily, and when such a reform becomes a reality, then, indeed, and not until then, will we have a city of the sanitary condition of which we can justly be proud.

MEDICAL EXPERTS.

This subject has been written upon, time and time again, and yet no progress has been made toward remedying the abuses that exist in the present manner of calling medical experts. To say that it is impossible to procure a fair and unbiased opinion on any intricate expert question, from a gentleman called and paid by one party to a litigation, seems like a slander upon the honesty and integrity of all experts. While this statement is eminently true, it is not really a slur upon the distinguished men who are sometimes summoned as experts, for the following evident reason: We are all human, and none of us perfect. It is almost impossible for the average man to help but have his mind influenced more or less toward the side who look to him for vindication, and from whom he is to receive the remuneration for his labor. Unconsciously to himself, his mind will be influenced in small details, and where there is room for doubt he will be very apt to give the benefit of the doubt to his own side. The abuses that are possible under the present system seem to be recognized by all, yet for some unaccountable reason there seems to be but little effort at reform. Again, the obstinately maintained differences of opinion expressed by the experts on either side, the one oftentimes diametrically opposed to the other, must have a tendency to place our noble profession in a ridiculous light before the unthinking public. This fact was well illustrated in a case recently tried in Scotland. A man injured on a railway brought suit against the company, and experts were called by either side. Their testimony was so conflicting that the judge, when addressing the jury, said that "the medical evidence was unsatisfactory, and left on the mind a distressing impression that the science of medicine was a science simply of guessing and experts. They had had doctors examined, who, with equal confidence and dogmatism, expressed contrary opinions upon the same condition of things, with no hesitation whatever; no scruple about expressing the clearest opinion of what was and what should be. The jury must therefore exercise their common sense, and throw overboard the medical opinions of those medical gentlemen, if they thought the greater part of it was guessing, and come to the facts." It is both unfortunate and unpleasant that such scathing censures should be passed upon our profession when we are not really the ones to blame. Every physician willingly admits that medicine is not an exact science, and that, therefore, differences of opinion on medical questions are not only natural but must be. But it is these public exhibitions of divergent views before those who, on account of the want of medical training, are unable to thoroughly appreciate why such differences should exist, that bring us, as a class, into so ridiculous a position. There is but one remedy for this morbid condition, and that has been pointed out and recommended by the American Medical Association. We must have legislation that will empower the court to call experts, denying absolutely this privilege to either side. Thus can the unbiased, uninfluenced and impartial expert calmly and scientifically render his evidence from an unprejudiced standpoint, and thus will the ends of justice be more efficiently served, and the dignity, respectability and honor of the medical profession be vindicated.

NOTES AND COMMENTS.

Tertiary Syphilis in Childhood.

When syphilitic symptoms are observed in childhood toward the period of puberty, it always becomes a question to determine whether the symptoms are due to congenital or acquired syphilis.

Roussel, in a recent work, shows that Ricord in France and Henry Lee in England, admit that

hereditary syphilis may appear several months and even several years after the birth of the child. The opinion of Ricord regarding the transformation of syphilis into scrofula is well known; and Erasmus Wilson, Bœrensprung, E. Wagner and Veiel admit that hereditary syphilis leads sometimes to lupus, sometimes to scrofulous manifestations, an opinion which has been combated by Hebra, Virchow, and Kaposi.

As regards the period of infant life when the symptoms of hereditary syphilis appear, MM. Trousseau and Laségue, as early as 1847, combated the opinion of those authors who admitted that the manifestations of the constitutional malady might appear after several years; they assigned the seventh month as the extreme limit.

M. Roussel shows that hereditary syphilitic manifestations generally appear during the first, second or third month after birth, and is of opinion that in most of the reported cases of tardy hereditary syphilis the disease was contracted after birth. This may happen through direct contagion from another child, or from relatives, or from criminal attempts, and such cases are more frequent in the crowded tenement houses of large cities than is generally believed; the author gives a number of such cases. As regards the treatment of such cases, M. Roussel affirms that he has obtained excellent results from iodide of potassium, carrying the dose as far as 150–180 and even 210 grains per diem, for a child from 9 to 18 years of age.

Syphilis and Alcohol.

In a recent memoir published in *la France Médicale*, M. Barthélemy calls attention to the exceptional gravity of syphilitic skin eruptions in patients addicted to the habitual use or abuse of intoxicating liquors. The observations which he gives were all collected while the author was chef de clinique in Fournier's service, and relate exclusively to the waiter girls employed in "brasseries," who receive the name of "inviteuses," because it is their business to have as much liquor ordered as possible. In the pursuit of this métier, they are obliged to drink large quantities of intoxicating liquors; one of them absorbed in one day forty-two glasses of beer, five liqueurs and one "grog Americain;" this, of course, was an exceptional case; but most are continually drinking, in order to incite customers to order for them. When these girls contract syphilis, every symptom, even the primary chancre, is of gravity. In one case the eruption did not disappear from the cutaneous and mucous surfaces for ten years. The chancre in one case spread and became as large as a silver dollar, and was surrounded with an extremely indurated border, and notwithstanding treatment, the chancre lasted three months. In another case (Obs. III) the chancres were still present when a generalized papulo-hypertrophic eruption appeared over the whole body.

It was remarked also that secondary and tertiary eruptions appeared much more rapidly, were of greater intensity and of longer duration.

The moral is obvious; according to one of themselves, "almost all the 'filles de brasserie' are affected;" and the same is undoubtedly true of the waiter girls in the bar-rooms which disgrace our large cities.

Wire Ligatures for Divided Bones.

Dr. T. Sympson records two cases in the *British Medical Journal*, wherein he obtained excellent results in approximating divided bones with wire ligatures. The first case was a crushed foot; he amputated according to Pirogoff, and fastened the os calcis to the tibia by iron wires. The operation wound was completely healed in ten days, but the wires were left in six weeks. The second case was a resection of the knee joint. The femur and tibia were brought firmly together by two iron wires, one on the outer, the other on the inner aspect; a most complete union was obtained. The operations were performed under antiseptic precautions, and the wire caused no irritation. It is desirable that the apertures made by the drill should be at least a quarter of an inch from the sawn surfaces, and that these surfaces should be very accurately approximated by twisting together the ends of the wires; not more than twice, however, otherwise difficulty will be experienced in removing them. Iron wire, such as that used for the stilets of elastic gum catheters, in size about No. 22 of the gauge, will usually be found the best.

New Treatment of Irreducible Hernias.

In the *Gaz. des Hôp.* (March 25, '82) Dr. Phil. de Saint-Maudé recommends the treatment of irreducible hernias with the hypodermic injection of muriate of morphia. Already, in the year 1877, Phillippe reported three cases, in which, after repeated and fruitless endeavors to induce taxis, the reposition of the hernia became possible on the hypodermic injection of the remedy mentioned. Phil.'s pupil, Boussenot, has now published an article in which he reports five new cases. In all of them reposition became pos-

sible after five to six drops of a two per cent. solution—repeated every fifteen minutes till success was complete—had been injected under the skin over the hernia. These were all cases in which all previous attempts at taxis had been useless, and in two of the cases symptoms of strangulation had already made their appearance.

As there cannot be any possible danger connected with these hypodermic injections, if performed with the usual care, it would be well to try them in all such cases, before proceeding to an operation which, under the most favorable circumstances, will always be attended with more risk than a successful taxis. The question in our mind is only this, if it would not be far better, after *one* fruitless attempt at taxis, to have recourse immediately to the hypodermic injection of morphia, instead of making repeated useless trials, which can only make the later success more doubtful, and irritate the parts more than seems necessary.

Application to Corns.

A correspondent complains that he has not been able to employ Dr. Traill Green's mixture for corns, recommended in the REPORTER, July 8, as it became solid, and could not be applied with a brush. His letter having been referred to Dr. Green, the latter writes:—

"I have never heard a patient say that it cannot be applied with a camel's hair pencil. If the bottle is not kept closed the collodion loses its ether, and the mixture loses its fluidity. The specimen referred to above has been standing for several weeks, and has lost none of its fluidity, and can be applied with a soft brush with perfect ease. I am surprised that any one should have any difficulty in preparing or using it. If I had discovered any special treatment in its preparation I would have stated it. If any one has not succeeded there must be an error in weight or something wrong in the materials. If any find their mixture wanting in fluidity more collodion than the quantity named will give it that property, but I have not had occasion to use more."

Dr. Green forwards us a bottle of it, and it is certainly fluid, and could readily be applied with a brush.

Heat and Health.

A respected New York physician writes us in quite severe terms, about our editorials on the relations of heat to life. He claims that the heavy July mortality was owing *directly* to heat. But he adds:—

"Esculents suffer a speedy decay, for lack of moisture, by the fierce rays of the summer's sun. This extreme favors and hastens fermentation and decomposition, putrefaction fills the air with the effluvia of sewers, cesspools, and drains, which man cannot endure with safety to life."

This, however, is just the point we make—that it is largely the *indirect* effects of the heat, as those he here mentions, which increase the death rate. For a New Yorker, he takes a rose-colored view of his city. Thus he writes:—

"Milk is cheap, excellent, and abundant here."

We recommend to him a little closer study of the sanitary statistics of his own city. Here is an extract from a New York letter of August 19th, in a Philadelphia paper:—

"Dr. E. H. Bartley, chemist of the Brooklyn Health Department, has rendered a report of his analysis of milk from swill-fed cows, and he says that the milk is of such a dangerous character that it should be strictly kept from the market. The report also cites two instances where children fed upon such milk died from its effect."

It is notorious that thousands of gallons of swill milk are sold in New York city every day.

Boiled Milk in Summer Complaints.

Dr. H. V. Sweringen writes to the Cincinnati *Lancet and Clinic*, emphatically condemning the advice, so often given, to boil the milk administered to children suffering from summer complaints. He objects to this procedure because boiling will coagulate the albumen, thus rendering it very difficult of digestion. He is right. *Boiled* milk is utterly unfit for children; but since the majority of children will refuse milk when it comes cold out of the refrigerator, it will be well to place the cup or bottle containing the milk into a pan of warm water for a few minutes; this will remove the chill, without coagulating the albumen.

Sanitary Inspection of Schools.

It is well remarked by the *Public Ledger*, of this city, in view of a proposed step in advance in public hygiene, that at any rate one item estimated for by the Board of Health should be allowed by Councils. This is the $6000 asked for sanitary inspection of the public schools by educated physicians. It is not to be supposed that such inspection is required only to ensure proper ventilation, heating, cleanliness of the buildings, etc., but it is also to protect the school children from scarlet fever, diphtheria, varioloid, smallpox and other contagious diseases. No estimate yet proposed by any department can be put to better use. The Belgian city of Brussels sets Philadelphia a good example in this matter.

Special Reports.

NO. X.—OPHTHALMOLOGY.

BY CHAS. S. TURNBULL, M.D.

A Case of Quinine Amaurosis Manifesting Itself Primarily in One Eye. *Arch. Oph. Vol.* XI, *No.* 1.

C. M. Hobby, M.D., Iowa City, Iowa, reports the case of a young lady, aged twenty one, in whom, for severe left supra-orbital neuralgia, subsequently, what was supposed to be episcleritis of the left eye occurred, accompanied by conjunctival injection and œdema of the eyelids. The neuralgia being considered malarial in character, was treated with large doses of quinine, and fomentations of belladonna were applied to the eye. Large doses of quinine were required, to produce cinchonism. Patient was anæmic, and on ophthalmoscopic examination, both before, and still more markedly after, the administration of quinine, ischæmia of the retina was noticed.

At the time the patient came under my observation she presented an anæmic appearance, had very little appetite, and was still suffering from occasional attacks of neuralgia. There was no injection of the conjunctiva or sclerotic; the right eye was apparently normal; in the left eye the pupil was widely dilated, and not appreciably affected by light. Right eye $= \frac{16}{xxxii}$; Left eye $= \frac{3}{cc}$. On the fourth day following she returned with both pupils dilated to the utmost. R. $\frac{16}{cc}$; L. $\frac{3}{cc}$. At this time she reported that the left eye began to get worse upon her return home, but she noticed no trouble with the right eye until the previous day.

Recognizing the probable existence of quinine amaurosis, Dr. Hobby commenced the use of strychnia hypodermically, increasing the quantity each time, until the physiological effects were apparent. The improvement was rapid, and in ten days the acuteness of vision had returned from $\frac{6}{cc}$ to $\frac{16}{xx}$ for both eyes, and the visual field of each eye, which had been reduced to about one-tenth of the normal, had doubled. During the use of strychnia the malarial symptoms disappeared, and the general physical condition improved. Six weeks later the acuteness of vision was unchanged and the visual field much increased in extent, but still less than half the normal

The inference to be drawn from this case would seem to be that the toxic effect of quinia primarily manifests itself in a single eye.

As there were symptoms of an episcleritis and supro-orbital pain of the left eye, and as belladonna had been used and the light had evidently had an irritating effect upon the retina of that eye, we would prefer to infer that in one congested, if not inflamed, eye of a pair to be affected by poisonous (toxic) doses of quinia, amblyopic symptoms are primarily manifest in the weaker eye of the two, both of which must sooner or later participate in the toxic amblyopia.

H. Derby, M.D., of Boston, reports (*Arch. Oph.* Vol. XI, No. 1)

Three Cases of Hydrophthalmus Treated with Iridectomy,

which he prefaces by the following remarks:—

"Cases of hydrophthalmus, cornea globosa, are as rare as they are unpromising. In the record of twenty years' practice I found but five instances of this disease. The only treatment seriously proposed has been iridectomy; and the encouragement to the performance of this operation has been given on grounds that are mainly theoretical. Instances of its performance have rarely been published. In his monograph on the subject,* written in 1869, Muralt states that he is not aware of any results having yet been recorded, and gives, himself, the notes of a single case. He admits that the operation is, in this disease, attended by unusual danger as regards healing and the chance of hemorrhage. And Schmidt, writing in 1877,† says "The secondary glaucoma which complicates cornea globosa (hydrophthalmus congenitus) offers a poor prognosis for iridectomy. Besides the danger of cyclitis, which may be easily excited by this operation, there are perilous possibilities of purulent infiltration of the vitreous, or of choroidal hemorrhages. When in these cases the rapid increase of intra-ocular pressure renders some kind of action necessary, it is best to try the effect of repeated paracentesis, which is certainly free from danger."

As we stated in the outset, the disease is very rare. Operations for its relief are, however, so much rarer, and so infrequently reported, that these cases here cited may well serve as a basis for generalization. They show that iridectomy, undertaken at a late stage of the affection, is liable to be complicated by hemorrhage, and to leave the eye in a state of chronic and painful irritation. But it cannot be denied that the disease is arrested, and that an amount of vision that was rapidly becoming extinct is spread over a series of years, to the great comfort of the patient. Case one had already lasted 14 years, and there was distinct optic-nerve atrophy at the time of the operation. Case two at least ten. Case three was taken in an early stage, and the

* Über Hydrophthalmus Congenitus. Zürich, 1869, p. 50.

† Graefe-Saemisch, Handbuch der gesammten augenheilkunde, vol. v, p. 136.

disease at once stayed. Eleven years have elapsed and no progress is manifest. I feel, therefore, justified in dissenting from the writer in Graefe-Saemisch, and in advising iridectomy.

Dr. J. L. Thompson, of Indianapolis, Indiana, records some "Practical Remarks on the Extraction of Foreign Bodies from the Iris."*

In the December number of the *Archives of Ophthalmology*, Vol. x, No. 4, Dr. Hirschberg, of Berlin, in his article on the

Extraction of Chips of Iron and Steel from the Interior of the Eye,

quotes from the London *Lancet*, as follows:—

"On May 18th, 1859, a girl, aged fourteen, was brought to St. Mary's Hospital, under the care of Mr. White Cooper. The previous day, while standing near her father, who was turning a piece of hardened iron in a lathe, a chip struck her left eye, which had since been in constant pain, though the sight was not materially affected. The chip was sticking in the iris, almost midway between its upper border and the pupil. The anterior chamber was full, and there was no mark of entrance in the cornea. . . . . Mr. White Cooper, fearing that difficulty would arise in grasping the smooth metal with forceps, suspended as it was in the loose membrane, decided on trying the effect of a magnet. The iris having been brought under the influence of atropine, whereby the foreign body was drawn near the margin of the cornea, the patient was chloroformed, and a cataract knife was passed through the cornea opposite the chip, and a sufficient opening made for its escape. A magnet was then applied to the wound, and in an instant the chip leaped from its situation in the eye and attached itself to the magnet. . . . . The eye was well in a week."

To the majority of the readers of the *Archives*, doubtless, the report of this case without comment will do no harm; but to the inexperienced it is likely to work immense mischief, by causing them to use atropine in similar cases. Yet we think that the end by no means justified the means used. The following case will show what dangers attach to the use of a mydriatic where foreign bodies lie in the anterior chamber.

W. F., aged 40, came to me in 1875, two days after the receipt of an injury to his right eye while hammering the iron hoop from a paint keg with the blade of a hatchet. A small piece of either the hoop or the hatchet flew into the eye, passing through the cornea and lodging in the stroma of the inner lower portion of the iris, midway between the ciliary and pupillary margins. The corneal wound had entirely healed, leaving scarcely a trace of opacity. His vision was good and he suffered but little pain. I proposed removing it, with probably a small portion of the iris, but he went off, promising to return shortly. I saw nothing of him for two days more, when he presented himself again, with the iris fully dilated and the body forced into the lens. I asked him how he came to use the atropine, and he replied that he had been reading "Gunn's Domestic Medicine." A well-marked opacity of a portion of the lens so obscured the metal that it could not be seen. Of course, I did nothing further than to watch and wait further developments. The last time I saw him, which was about two months after the injury, the lens was almost totally cataractous, with no inflammation remaining. He then passed from under my notice.

In the above case, by sacrificing a very small portion of the iris, he could have been given useful vision, and probably even without said sacrifice; but after the use of the atropine the body was forced through the delicate iris, the lens wounded, and now, of course, if anything is done it must be the removal of the lens, a very questionable operation where the other eye is not aphakial.

How would atropine have acted in the following case?—

White, Joseph, aged 28, a stone-cutter, was wounded while dressing a stone with hammer and chisel, Jan. 31st, 1880. He immediately went to a "Surgical Institute," where, he says, they worked on him every day until he came upon me, on Jan. 5th, 1881, when I found a foreign body lodged on the upper pupillary margin of the iris, about three fourths of it upon the iris and the remainder hanging over and into the pupil. I placed him under chloroform, made a section of the cornea at its junction with the sclerotic, and removed the body, with a small portion of the iris, without any difficulty whatever, before the class, at our City Hospital. The operation was made on Saturday, and he read in the presence of the class on the following Wednesday. Now, had one used a mydriatic in his case, the body would as surely have been stripped off of the iris and against the lens, as was the foreign body forced through the iris, in the case above mentioned.

I have simply reported the two cases to show the danger of the use of atropine where bodies are imbedded in the iris. Many others, where

* To those of our readers who are settled in either a manufacturing or a mining district, we would call especial attention to Dr. Thompson's eminently practical remarks and valuable hints on the use of atropia. C. S. T.

percussion caps and pieces of iron have been so placed, have I, as well as all other eye surgeons of experience, had to do with, but their mention in detail would be unprofitable and superfluous.

Rupture of the Eyeball in its Posterior Hemisphere, from a Blow in the Face (*loc. cit. p.* 45).

By Julian J. Chisholm, of Baltimore.

The two cases of recent occurrence which I here report, although novel in my personal experience, would not have had publicity beyond the staff of the Presbyterian Eye and Ear Charity Hospital, before whom the diagnosis was made and verified after extirpation of the destroyed eyeballs, had I not found in a recent work on "Injuries of the Eye," by Ferdinand Von Arlt, a recognized authority on such matters, the following passage. I make the quotation from a translation of the German work by Dr. Chas. S. Turnbull, an American publication.

A paragraph on page 37 reads as follows: "Cases of rupture of the sclerotic are not rare. Such rents extend, without exception, to the ciliary body, even through it. Of ruptures in the posterior and sclerotic area, only one case is recorded (by Bowman), and here the rupture was not recognized until after the eyeball had been enucleated."

From the same work I make an extract from pages 22 and 23: "When a foreign body impinges against the eye with a certain degree of sudden force, and, on account of certain physical properties, such as size, bluntness, etc., cannot perforate its tunics, it expends this force by contusing the surface against which it strikes, or it causes either flattenings or indentations, the degree or extent of which depend on the character of the injuring surface, while, in the moment of injury, perhaps, no movement of the eyeball, as a whole, takes place. Now, an indentation or flattening of the eyeball cannot plausibly be considered possible, unless the same also changes its form *in toto*. Suppose we consider the point attacked as the pole, and the direction of the attacking force as the axis of a sphere; then the equator of the latter must become longer at the moment of the injury. Any resistance at the opposite wall, especially if distributed over an extensive area, will only serve to increase this change of form. The occurrence of a gap in such a wall, or of a projection upon it, will, when the globe is pressed against, produce a localized bulging—in the former case corresponding in shape and dimensions to the gap, and in the latter to an indentation or perforation of the sclerotic; *but such conditions hardly, if ever, occur.*" Sclerotic rupture is of *rare or non-occurrence* in those very localities where choroidal rents are most frequent." Again, from page 27: "The constant parallelism of the sclerotic rent to the corneal margin has an additional reason in the histological fact that the fibres of the sclerotic coat run parallel to the latter, within the confines of the ciliary region." Again, at page 38, "The sclerotic rent is linear or slightly arched, more or less serrated, and usually runs parallel to the limbus cornea, at a distance from two to five millimeters from the latter. In one case only (Schrœter, *Klinische Monatsblätter*, 1866, p. 248) did the rent run at an acute angle."

The following extract is made from a standard work on

Eye Injuries,

by George Lawson, F.R.C.S. "The split in the sclerotic is almost invariably near the margin of the cornea."

Case 1.—N. L., aged 27, was struck in the left eye with a chair, during a drunken broil. He was knocked down insensible, and had his nose and brow badly cut. When he came to himself he was taken home. In the meantime the eyeball had become very prominent, from swelling. He complained of great pain in it, and also of loss of sight. He was brought to the Presbyterian Eye and Ear Charity Hospital, for treatment, on the day after the accident. I found the eyeball very protruding, with lids much swollen and firmly stretched over the projecting ball, which was half exposed. The conjunctiva was much discolored with blood extravasation, and was chemosed in a heavy fold, parallel with the free border of the lower lid. When the lids were drawn apart the eyeball protruded so conspicuously as to show the whole anterior half of the sphere, and presented the condition known as paraphimosis of the eyelids. When thus exposed, the whole front of the eyeball was entire, apparently without any injury to its outer walls. The anterior chamber was full of blood, and there was no perception of light. I was induced to palpate the eye, and found its tension decidedly minus. It was so soft that the cornea could be corrugated, a condition that could not exist in connection with the intra-ocular hemorrhage without a giving way of the eyeball and the escape of some of its contents. Upon this diminished tension and excessive blood extravasation, with great prominence of the eyeball, I diagnosed laceration of the posterior hemisphere of the sclerotic. To prevent future suffering, I advised enucleation, which operation was satisfactorily effected, under chloroform. After making the conjunctival section around the cornea, the opening of the capsule of Tenon to reach the tendon of the external rectus muscle allowed the escape of a quantity of dark fluid blood, and indicated the location of the scleral opening, which an examination of the eyeball after its removal confirmed. The rent, which was a large flap, opening in the outer wall of the sclerotic, was located in the posterior hemisphere of the eyeball, between the insertions of the external

rectus and the oblique muscles. The source of hemorrhage was choroidal. The blood, after filling the eyeball and displacing the lens and vitreous body which had escaped through the sclerotic rent, had freely effused itself into the orbital space, and by excessive infiltration had caused the extrusion of the eyeball.

This was the first case that I ever diagnosed, in the absence of any visible wound, as posterior laceration of the sclerotic coat of the eyeball, as I was surprised at the facility with which the diagnosis could be made. The eyeball, full of blood, with excessive extravasation under the conjunctiva, and accompanied by marked minus tension, made the diagnosis very positive, of escape of some of the eye contents through a wound concealed from view.

I had been very much surprised, on previous occasions, at the amount of bleeding which could take place from a sclero-choroidal wound. In one, a case in which the eyeball had been perforated by a fragment of iron over the insertion of the superior rectus muscle, I had much difficulty in checking the profuse bleeding from the wound, which saturated thick compresses. I was, therefore, quite prepared for the excessive extravasation in this case. The accident just reported, of posterior scleral laceration, was from a blow received, through the lid, upon the elastic eyeball, resulting in the giving way of the eye-coats at a point nearly opposite to that upon which the blow fell; clearly a case of laceration by counter stroke, and at a point where the eyeball is well supported by muscles as well as by the fatty cushion of the socket.

This accident was the sequel of a Christmas frolic. In accordance with the experience of every surgeon who finds rare cases running in company, the day after New Year another case of eye injury, nearly similar in its results, was brought to the hospital dispensary for treatment.

Case 2.—I. F., aged 23, was wounded in the right eye, under the following peculiar circumstances: He and a friend were discharging pistols at a mark. While the patient was loading his revolver, his companion, standing near him, fired at a stone lying on the ground some ten feet in front of them. With the report of the pistol the injured man cried out that he had been shot, which remark caused much merriment, from the apparent impossibility of such an accident, as the shot had been fired away from him. Blood was seen, however, upon his face, oozing from a wound in the upper lid. The eye immediately commenced to swell. He complained of great pain, and said that his sight was knocked out. I saw him the day after the accident. The eyeball was very prominent, with excessive ecchymosis of the conjunctiva and with the anterior chamber full of blood. The pistol ball, in rebounding backward from the stone, had struck the lid, but not with force enough to penetrate. The skin of the upper lid only was broken, and from it the blood had escaped. The eyelids were much stretched over the protruding eyeball, and a fold of discolored, chemosed conjunctival tissue seemed to fill up the palpebral cleft. I elevated the lid upon a retractor, and found that there was no wound in the front of the eyeball, and yet upon palpation I found the tension very much diminished, so that I could corrugate the cornea. With the case of a week before fresh in memory, I did not hesitate to make the diagnosis of posterior rupture of the sclerotic coat of the eyeball, and recommended immediate extirpation of the destroyed and painful organ, as the quickest means of obtaining relief from suffering and safety for the other eye. Under chloroform the eye was enucleated. The eye-shell was found full of coagulated blood. Its normal contents had escaped through a large rent in the upper part of the ball, which opening extended backward from the insertion of the superior rectus tendon. The tendon of the muscle restricted the laceration to the posterior hemisphere of the eyeball, and prevented the wound from being seen when the eye was examined, before the operation.

The laceration seemed to have started from the point of the eyeball upon which the blow impinged, and had extended directly backward. An explanation for this rare accident may be found in the fact that when the injury was received the wounded man was loading his pistol, and was looking down toward his hand. He, therefore, had not only the eyeball well covered by the upper lid, but in the extreme downward movement of the eye a large part of the upper hemisphere was rotated forward and exposed to receive the blow. The pistol ball must have been somewhat spent, as it only broke the skin of the lid; but the blow was sufficiently sudden and sharp to indent the eyeball to splitting, and thereby make the rent through which the contents of the eye were projected into the socket and incarcerated within the cone of muscles.

These two cases, while rare accidents, at least as far as the establishing of a diagnosis is concerned, differ in the immediate cause of the rent. In the first case the laceration in the eye-coat was not in a portion of the eyeball brought immediately under the influence of the blow. When the man was struck in the face by the chair, the bruised temple, brow and nose indicated that the blow was received directly across the eye, upon its front, through the medium of the lids. The common seat of laceration near the corneo-scleral juncture did not yield, although this was nearest to the surface receiving the blow. When the sudden flattening of the eyeball took place the rent occurred near the opposite pole of the eye impinged upon. In the second case the rent started at the point receiving the blow, and extended backward in the direction of the posterior pole, and at right angles to the so called circular laceration around the corneal periphery.

Correspondence.

An Interesting Obstetrical Experience.

Ed. Med. and Surg. Reporter:—

Very early one March morning, two years ago, I was called twelve miles northwest of this city, to attend Mrs. M., in labor. I had never seen Mrs. M. before, in fact had never heard of such a person before, and consequently knew nothing of her previous history, or very likely I would have invented some excuse to have remained at home. Before that Sunday had wholly passed I had been tempted fully a dozen times to commit suicide in order to escape the dreadful burden of my existence then and there.

Mrs. M. was a small, emaciated, frail, exceedingly nervous woman, about thirty years of age, and this was her second confinement. The first, I learned by snatches during the day, was attended by a physician in Illinois, from whence the family came, who devoted several days to its completion, and whose moral character, in consequence, was forever wrecked thereby.

Mrs. M. was in bed when I arrived, neatly encased in a highly embroidered night-gown, frilled and tucked, and inserted with lace, quite up to her ears, and surrounded by the entire matronly force of the neighborhood, her large, black, searching eyes blinking like live coals, and her tongue going at the rate of one hundred and twenty strokes to the minute. The manner in which she had all of those women employed in waiting upon her would have outwitted the ingenuity of mortal man. Her pains were not worth speaking of, but as they came straggling along at the rate of one every half hour, she dextrously managed to overcome the whole loss of valuable time during such intrusions by drawing down the side of her face furthest removed from her friends, and nodding and smiling and endeavoring to keep up an unflagging interest in the general conversation with the side nearest to them. Whenever I attempted to make an examination, in order to determine, from time to time, how we were progressing toward some ultimate hope, she flinched and screwed herself in bed, and made things so decidedly uncomfortable for the entire household, that I had to desist and take my observations mentally. Moreover, such efforts always "chased away the pains," as she expressed it, and she would lie, in consequence, for hours, frequently, without even a twitch to disturb the muscles of her face. I passed the first few hours, until dawn, in fact, in desperate efforts to count the "ticks" of the clock. I was never so thankful for dawn in my life.

If there had not been some material changes in her pains about this time I truly believe I would have gone insane; but, as it was, however, these became a little more severe and prolonged, and I was thereby saved from an untimely grave. Her tongue, however, never ceased for a moment its usual rate of speed, and her perception of touch was more keenly alive than ever. Vainly, time and again, did I endeavor to administer ergot. The mere smell of the drug brought her stomach in such close proximity to her mouth, and her tongue so nearly assuming an attack of St. Vitus' dance, that I feared danger, and desisted, only to resume my mental observations. By the time the child was born, near nine o'clock that night, my hands were a mass of raw flesh, from my wrists to my elbows, from the prolonged pulling they had received from time to time at the hands of that woman; my coat was nearly off my back, in pieces; part of my suspenders gone; one whole sheet used up in the same pulling; the entire neighborhood completely worn out and speechless, from sheer exhaustion, and the woman herself only the ghost of a possibility. Moreover, the child was *atelectacic;* quite dead, I thought; placed in an old shawl for ten or fifteen minutes and laid by for dead, and only discovered to possess the faintest trace of life some time afterward, *accidentally*. By throwing cold water into his face frequently and repeatedly, however; by prolonged expansion and compression of the chest; by breathing into his mouth at intervals, and by spanking him lively over various portions of his body, sufficient life was manifested during a half hour's earnest work to insure safety. The child is well and hearty to-day, and I vaccinated him this summer. Charles H. Miller, M.D.

Peabody, Kansas.

Administration of Ether.

Ed. Med. and Surg. Reporter.

In your issue of August 5th, I read with interest and some profit a selection headed "Ether vs. Chloroform" (page 151). The subject is one of deep importance to every practitioner, but as country practitioners have not the same opportunity of making themselves acquainted, practically, with new methods, articles like the one referred to excite in them a greater degree of interest than in the city practitioner, whose opportunities for seeing are commensurate with his desires. The comparative merit and safety of ether are now established, beyond all reasonable doubt. So firm a hold has this fact taken of the mind of the profession, that I believe chloroform would be but rarely used, but for the facility of its administration, and conversely, the difficulties encountered in administering ether. Let us have a ready and satisfactory method of administering ether, and but few will adhere to chloroform.

In the selection, from the *British Medical Journal*, above referred to, the writer, who appears to have had large experience, recommends Clover's apparatus as the one thing to be desired in administering ether. Now, I know nothing about this rubber bag, nor any other bag of similar use or application. I cannot afford to go hundreds of miles to see one and witness its use in the hands of an expert. It is clear ether cannot be successfully and economically administered on a towel.

Now, will somebody of large practical experience rise and tell us some practical things about giving ether. We country practitioners want to know what apparatus to use and how to use it. We also want to know its cost, for we are not all rich. Let no one rise to explain who has a patent bag of his own, or who has a friend who owns one. Ontario.

The Electric Bath.

ED. MED. AND SURG. REPORTER:—

Some editorial criticisms on the use of the electric bath appeared in a weekly medical journal of your city, to which I replied; but as, evidently, the editor preferred his *ipse dixit* to enlightening his readers, he declined to admit my reply. As it is really a subject of general interest and therapeutic importance, I send to you the correction of the errors which that editor did not like to print, owing, no doubt, to an easily understood weakness of the human organization.

The portion of the editorial remarks which suggested this communication, was as follows: "The reason why it," the electric bath, "is regarded by all scientific electricians as a faulty method, is, that water offers such a powerful resistence to the passage of the current that the patient immersed receives too little to be effective." It must be admitted that theoretically this is entirely true, and that it is frequently reiterated by those who have little familiarity with the electrical bath. During the last few years I have seen considerable of the application of electricity, some 5000 applications in four years, nearly half of which were through the medium of the bath.

For the purposes of the bath the faradic current, almost exclusively, was used. The remark that the "patient immersed receives too little to be effective," shows ignorance. If the patients' nerves are to be relied upon to indicate the amount of electricity, and incredulous, stoical men may be taken as the subjects, as much electricity can be given with a large one cell induction battery as a patient can bear. A few—a very few, can stand the full strength of the instrument, and I have met with no one who has taken the bath, who denies the presence of a strong current when it has been desirable to give it. If "too little to be effective" be more than any ordinary person can stand, it must be admitted that the claims of the editorial are well founded. The strength of the current can, of course, be moderated from great intensity to as slight a degree as desired, precisely as out of the water.

For effectiveness, however, a large battery is not needed. I have replaced the ordinary stationary battery with a light, two-cell portable one, manufactured by the Galvano-Faradic Co., and the effect was nearly, if not quite, as marked as when the former was used. The experience with this current in the bath was detailed with some minuteness, in a recent number of the MEDICAL AND SURGICAL REPORTER, and scarcely requires repetition in this letter.

Since reading the editorial referred to, in order to clear away any possibility of doubt, and to secure, if possible, more convincing data, I have been making some experiments with the galvanic current and a galvanometer in connection with the tub. The distance across the tub, between the electrodes, was twenty to twenty-four inches, varying with the slant of the side.

The distance diagonally, as experimented with, four feet. The depth of the water, both with the person in and out of the tub, was kept at eleven inches. The electrodes extended constantly nine inches into the water, and were of plates of copper; the tub being of wood. The body of the person when in the water was two to four inches from the electrodes, and the feet six or more inches. The temperature of the water was 94 Fah.; and the number of cups (modified Daniels) twenty. The galvanometer is of Trouvé make (Paris), and a good one. The result was as follows:—

Direct across tub without person in, gal.				39 to 41
Diagonally	"	"	"	34 to 36
Direct	"	with	"	42 to 43
Diagonally	"	"	"	38½ to 40
Poles of battery touching out of water			"	45
Current passed through chest			"	17

The experiments were repeated several times the same day with the same person. The figures would naturally vary somewhat when tried on different persons. Precautions were taken to avoid every apparently possible chance for fallacy. The purity of the water must also modify the result of experiments.

Five conclusions seem patent, from the foregoing: 1st. That a large amount of electricity passes through the water. 2d. That more passes through the water than passes through the person out of the water. 3d. That the person in the water conducts better than the water alone (see also Beard & Rockwell's experiment). 4th. That at least the difference, as indicated by the galvanometer, between the amount of electricity which passes through the water alone and when the person is in it, must pass through the person; and as it passes through the body more readily than through the water, probably much more than that difference passes through the person. 5th. It seems reasonable to consider the skin the chief medium of resistance when administering electricity, and that the bath largely overcomes this. Also that the reason that the body conducts better than pure water is on account of the large percentage of salts which are contained in its liquids.

In conclusion, I should be very glad to demonstrate the facts here claimed for any physician who may choose to call upon me.

W. O. STILLMAN, M.D.

Saratoga Springs, N. Y.

NEWS AND MISCELLANY.

The Lehigh Valley Medical Association.

The second annual meeting of the Lehigh Valley Medical Association, was held at Allentown, August 16th. This Association is composed of physicians from Warren Co., N. J., and the counties of Northampton, Lehigh, Bucks, Carbon and Monroe, in this State.

Dr. P. Reichard, of Allentown, read a paper entitled "Cases of Surgery from my Note Book." Dr. J. Ewing Mears, of Philadelphia, read a paper on "Observations on the Value of Modern Methods in Abdominal Surgery, with the study of the Results in Twenty-four Cases of Abdominal Section." Dr. Traill Green read a paper for Dr. Hiram Corson, on "Smallpox." Dr. Amos Seip, of Easton, recited some of the sights he had seen during his recent trip abroad. He

saw a speculum two thousand years old, which had been exhumed from the ruins of Pompeii, and which was very much like those in use to-day.

The following officers were chosen for the ensuing year: President, Dr. Traill Green, of Easton; Vice-presidents, Dr. Alfred J. Martin, Allentown; Dr. Amos Seip, Easton; Dr. Osman, of Warren county, N. J., and Dr. Joseph Thomas, Quakertown; Secretary, Dr. Isaac Ott, of Easton; Treasurer, Dr. Abraham Stout, Bethlehem.

The new president was inducted into office, and on taking the chair spoke of the progress the science of medicine has made since he entered the profession, and how much more lucrative it is now than it formerly was. After passing a resolution of thanks to the medical fraternity of Lehigh county, the meeting adjourned.

Sanitary Precautions for Canning Establishments.

Dr. W. S. Forwood, at the request of the Board of Health and Medical Society of Harford County, Md., has prepared an address to the canners of the county on the hygiene of their establishments. After reciting the usual rules of cleanliness and care in selection of fruit and vegetables for canning, it is recommended that the refuse be daily scattered over the surrounding fields, by which means it will be disposed of, at the same time that it fertilizes the ground. Attention is called to the occasional presence of lead in the tin from which the cans are made, and it is suggested that glass jars should be used in preference. Fresh lime or plaster should be freely scattered, every day, about the premises. The address contains many wise suggestions.

Philadelphia County Medical Society Lectures.

The annual course of lectures under the auspices of this Society will be given during the winter of 1882–83, by Prof. Austin Flint, Senior, of New York, who will consider subjects relating to the physical diagnosis of internal diseases.

OBITUARY NOTICES.

PROF. F. M. BALFOUR,

The distinguished Professor of Animal Morphology in the University of Cambridge, recently lost his life in Switzerland, as the result of an accident. With the national love for Alpine climbing so characteristic of Englishmen, Dr. Balfour attempted what has been called a most dangerous feat, which has terminated so disastrously. The late Professor, though but thirty years of age, was the most distinguished graduate Cambridge has had since the time of Clifford, and in his own special field of embryology he was without a rival. The deceased naturalist was a Fellow of the Royal Society, Royal Medalist in 1881, M.A. and Fellow of Trinity College, Cambridge, LL.D. of Glasgow University, and President of the Cambridge Physiological Society. He was a younger brother of Mr. Arthur Balfour, M.P. for Hertford, and nephew of the Marquis of Salisbury.

DR. WILLIAM ATWATER.

Dr. William Atwater, a physician of New York City, died at Centre Harbor, N. H., on the 13th of July, after a brief sickness with which he was stricken while on a visit to the White Mountains with his family. Dr. Atwater was born in Connecticut, about 65 years ago, and was educated for the medical profession. He was graduated at the College of Physicians and Surgeons, having Dr. Willard Parker as a preceptor during his student life. He served for several years as a physician in Bellevue Hospital and in the institutions on Blackwell's Island, and afterward engaged in a large private practice. The worry and strain of his professional work proved too great for his system, however, and fifteen years ago he relinquished active practice, and visited the coal and oil regions, becoming deeply interested in religious matters in that locality. He founded a Congregational church in Pennsylvania, and did much charitable work among the sick poor, whom he was accustomed to attend without fee. He leaves a family and many friends in New York by whom he was highly regarded.

DR. GEORGE R. DENNIS.

Dr. George R. Dennis died at his home in Somerset county, Md., August 13th. He was born April 8, 1822. Graduating at the University of Pennsylvania, he practiced medicine until 1855, when he retired, on account of ill health, since which time he has devoted himself to agricultural pursuits. He was in the State Senate in 1854, for the full term, and in 1867 was a member of the House of Delegates. In 1872 he was elected to the State Senate and resigned to take his seat in the United States Senate, to which he was chosen while a State Senator. Dr. Dennis was, in politics, formerly a Whig. He was a member of the Whig National Convention of 1856, which nominated Fillmore and Donelson. He was also a member of the Democratic National Convention of 1868, in New York, which nominated Seymour and Blair, and also of the Democratic National Convention which nominated Tilden and Hendricks.

DR. M. A. WILSON.

Dr. Milo A. Wilson, formerly of New York, died in Denver, Col., of Bright's disease, July 5th, 1882. He was born in Pittsburg in 1845, and was the son of the late Dr. R. A. Wilson, and brother of the late Oregon Wilson, the artist. He was at one time one of the surgeons of the Seventh Regiment and a member of the medical staff of Bellevue Hospital. While in that position he became particularly interested in the improvement of the condition of the insane, and made a number of interesting experiments to ascertain the effect of music upon the patients at Blackwell's and Randall's Islands. Dr. Wilson was the author of several medical books.

QUERIES AND REPLIES.

E. T. G. would be glad to have our readers give their experience in the treatment of spermatorrhœa; remedies used, etc.

180-eowtf

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

CHYLIFORM EFFUSIONS INTO SEROUS CAVITIES.

BY M. DREYFUS-BRISAC,

Physician to the Paris Hospitals.

The production, in certain serous cavities, of an effusion resembling chyle or milk was noticed as early as the beginning of the eighteenth century (Saviart, 1701); but these observations, including several reported by eminent clinical observers, such as Chomel, Rokitansky and Oppolzer, did not attract special attention; a complete study of the question was not made until Quincke published a memoir founded on the observation of three cases, in the *Deutsch, Arch. f. Klin. Med.*, 1875. An important communication on the subject was made by M. Debove to the Soc. Med. des Hôpitaux, May, 1881.

In the course of this work, M. Debove, after considering separately most of the observations scattered in different scientific publications, describes and criticises the two theories put forward to explain the production of such an effusion. He proposes instead of the appellations, milky, chylous or fatty effusions, successively employed to designate the disease, the denomination chyliform effusion, as having the advantage of not positively asserting the chylous nature of the liquid effused.* It is, then, with good reason that this designation has been adopted in two recent memoirs on the subject: the thesis of Mme. Perrée (Paris, 1881), a good résumé of all the documents we possess on the subject, and the interesting inaugural thesis of Ferdinand Veil on the "Pathogenesis of Chyliform Ascites," a work containing some original researches.

Under the same category may be considered several cases of benign, purulent pleurisy, reported in the Leçons Cliniques, of M. Gueneau de Mússy, and in the thesis by Sainton (Etude sur une varieté latente et benigne d'empyème, Paris, 1881).

Finally, we should mention, in order not to remain entirely in the domain of internal pathology, the interesting case of hydrocele, containing a fatty liquid, reported by M. LeDentu to the Soc. de Chirurgie (Dec. 14th, 1881), and the discussion it provoked at that period.

To resume, with the exception of one case in the tunica vaginalis, chyliform effusions have been found in but two serous cavities, the pleural and the peritoneal. The whole number reported consist but of ten cases in the pleural cavities, eighteen in the peritoneum, and two in which the effusion occurred in both serous cavities at the same time. From whence we may conclude that this morbid process is exceptional, though many cases may have passed unperceived or been wrongly interpreted. In chyliform effusions the liquid is bluish-white or yellowish, opaque, alkaline, with little or no odor, very much resembling emulsion of sweet almonds, and has no tendency to become coagulated when left standing.

Microscopical examination reveals the presence of fatty granulations and even larger collections, almost drops of oil and a certain quantity of crystals of cholesterin. The liquid contains no red globules; the pus globules

(leucocytes) are either entirely wanting or very few in number, and in a more or less degenerate or fatty state.

In some cases, as in the observations reported by Bacelli, microscopical examination alone can serve to distinguish the liquid from that found in ordinary empyema; as the fatty matters are in a state of emulsion these effusions will not be confounded with any of those collections of pus which hold in suspension a certain proportion of fatty corpuscles.

The chemical analysis of these chyliform effusions has been made several times, by Bergeret (*Journal d' Anat. et de Physiol.*, 1873) and by M. Yvon in M. Debove's case.

This last gave the following figures in weight per 100 parts: Coagulable albumen 68, cholesterine 3.8, fatty matters 3.4, nitrogenized products 1.50, mineral water 7.1, and water 13.6.

Chyliform effusions are ordinarily very abundant and are reproduced very rapidly, even after repeated aspirations. Thus M. Gueneau de Mussy took from the pleural cavity more than six quarts of liquid in eighteen days; while Quince aspirated three times in twenty-one days, taking away six quarts of liquid; the patient died on the same day the third aspiration was performed, and at the autopsy seven quarts of lactescent liquid was found in the pleural cavity.

The effusions into the peritoneal cavity were even more marked. Without speaking of Saviart's case, where two hundred and eighty-nine pints of liquid were withdrawn in nine months, we note that Veil withdrew by aspiration twenty-three quarts in twenty days, and Gaucher twenty-seven quarts in seven days.

On all these points the authors are in accord, but regarding the etiological conditions inducing this variety of effusion, its clinical characteristics and pathogenesis, the opinions widely differ, and there seems to be no means of arriving at a plausible solution of the problem.

The analysis of reported observations and the lesions revealed on autopsy afforded very imperfect data regarding the etiology of chyliform effusions. They have been observed at every age, from six months (Wilhelm's case) to sixty-three years (Debove), in individuals enjoying good health, as well as those in a cachectic condition.

Almost the same causes are recognized for a chyliform effusion as for an ordinary pleuritis; the effects of cold, a traumatism, excessive fatigue, and finally, in two or three cases, pulmonary tuberculosis.

As regards chyliform effusion into the peritoneum it seems to be produced under the same influences as ordinary serous ascites; for careful consideration of all known cases give as concomitant diseases, cirrhosis of the liver (four cases), simple chronic peritonitis (two cases), tuberculous peritonitis (five cases), cancerous infiltration of the peritoneum and mesenteric ganglia (three cases).

Finally the puerperal condition was considered to have a part in the causation, in one case of ascites (Chomel), and one case of chyliform pleurisy (Bacelli).

As regards symptomatology, we have no interesting peculiarities to mention, except in pleural effusions.

Chyliform ascites presents the same signs clinically as ordinary ascites, and the flow of a milky liquid during aspiration has been always a surprise to the operator. The course of the morbid process, or rather symptoms, depends not on the nature of the liquid effused into the peritoneum, but on the organic affection accompanying it. Or, as in almost all cases, the concomitant disease affects the entire system, or consists in some local disease tending to a fatal ending, such as tuberculous peritonitis or cirrhosis of the liver, it may generally be considered, when a lacteal liquid is obtained on paracentesis of the abdomen, that the prognosis is of extreme gravity.

The question, from a clinical point of view, is more complex as regards chyliform pleurisy.

The affection generally commences like acute pleurisy of ordinary intensity, but with this characteristic, that the local phenomena are most marked.

On account of the abundance of the liquid effusion, there may be notable enlargement of the thorax with compression of the lung and displacement of the neighboring organs, whence frequent and severe attacks of dyspnœa. Such symptoms call for immediate intervention, and aspiration is followed by very evident amelioration. The general symptoms are not urgent; there is but slight rise of temperature toward evening, no diarrhœa, no night sweats, in other words, no symptoms of hectic fever.

But as the chyliform liquid seems to have no tendency toward absorption, and is rapidly reproduced with all the symptoms of lung compression, etc., it is found necessary to aspirate frequently. It is the exception to observe a case where complete cure is obtained. If the general health remains comparatively good, aspiration may be repeated from time to time, each opera-

tion being followed by a period of amelioration, during which the patient may be able to follow up his usual occupations.

The march of the morbid process resembles that observed in chronic sero-fibrinous pleurisy, or rather in hydrothorax; but what seems to specially characterize chyliform pleurisy is the non-production of adhesions, or of false membranes which bind down the lung; so that when the liquid is withdrawn the lung may return to its normal position and recover the plenitude of its functions.

Such appears to be, as far as can be judged from the small number of cases observed, the clinical peculiarities appertaining to chyliform effusions of the pleura. So that the authors who attribute this form of pleurisy to a special metamorphosis of a liquid which was primarily purulent, are compelled to consider it a very benign form of empyema. (Gueneau de Mussy, Sainton.)

As a practical deduction from these facts, in any case where there is doubt regarding the purulent nature of a liquid obtained by aspiration, microscopical examination should be made, to determine whether or not it is a case of chyliform effusion; for in such cases the only treatment applicable is "Thoracentesis, with all the precautions judged necessary in cases where abundant effusion exists. The operation is necessary and may bring about complete cure" (Sainton). We will add that, as far as is known, there are no cases on record where the chyliform liquid became purulent.

The semeiology is very vague, and the question of pathogenesis still more obscure. In this respect we find ourselves in presence of two theories diametrically opposed to each other.

Some observers admit, with Quincke, that the chyliform liquid is really chyle, and that these effusions are due to the rupture of one of the chyliferous vessels or of the thoracic duct itself; others consider, with Gueneau de Mussy, Sainton and Veil, that the chyliform liquid is produced by the fatty transformation of an effusion which was at first of a purulent nature.

The theory proposed by Quincke has no foundation in fact, and we might say with Veil that "the rupture of any of the chyle ducts has been so exceptionally reported, and then with so little appearance of authenticity, that this cause can not be considered in the search for explanation of effusions of a chyliform nature."

Again, in several observations reported in detail, a circumstance is noted which is interesting in this connection; in certain cases of chyliform pleurisy, or ascites, there exists a certain amount of œdema of the limbs, and puncture of the skin at regions distant from the thorax gave issue to a lactescent liquid. It is difficult to admit that chyle escaping from the ducts could spread to such a distance in the cellular tissue.

In favor of the second theory, more positive arguments may be adduced. That the pus, deprived of the pyogenic germs (microbes) to which its activity was due, may undergo fatty degeneration, is not impossible, and a similar process has been observed in subcutaneous purulent collections. On the other hand, in a case observed by M. Gueneau de Mussy, it would seem that this metamorphosis did really occur, for the liquid, which at first contained pus globules in great numbers, assumed, later, all the characters of a chyliform effusion. We should, then, be willing to admit that this theory applies to certain cases; this would be a relatively favorable termination of pyothorax.

But how are we to explain the greater proportion of cases in which a lactescent liquid is obtained at the first aspiration?

How, in particular, are we to explain the production of chyliform ascites? Should we admit, with Veil, the existence of "a special form of purulent peritonitis?" We should hesitate to follow the opinion of this author, for this variety of ascites is observed in the course of affections, such as cirrhosis and chronic peritonitis, which generally give rise to ordinary serous effusion; and, again, the symptomatology does not serve to corroborate the hypothesis of diffused suppuration of the peritoneum.

It is, perhaps, in another direction that the researches should be pursued. There exists an observation, due to Winkel (*Deutsch. Arch. f. Klin. Med.*, vol. xvii), where, in a lactescent liquid developed in the peritoneal cavity an immense quantity of small entozoa were found. This patient, a female, had lived ten years at Surinam. This fact is, it is true, unique; but since it is at present proved that chyluria is frequently due to the presence of micro-organisms, would it not appear probable that certain chyliform effusions have an analogous origin?

In reality, it is a confession of ignorance we are obliged to make, and for the moment we are obliged, with M. Debove, to reserve the question of pathogenesis, and create among the varieties of effusion observed in serous cavities a separate place for the variety we have essayed to describe in this lecture, after the consideration of evidence as yet, unfortunately, very incomplete.

Communications.

A CASE OF ACUTE PERITONITIS.

Read before the Litchfield County Medical Association, at meeting of July 11th, 1882,

BY WILLIS J. BEACH, M.D.,

Of Litchfield, Conn.

Flossie H., aged 15, a bright, active, healthy girl, with no former illness and good family history. Was first seen June 7th, 1882, and presented the following symptoms and history: Pulse 134, temperature 104, severe headache and pain and tenderness in the right iliac region; parents stated that she had had as many as ten or twelve thin, greenish discharges from the bowels within the preceding twelve hours, but that previous to that her bowels had been rather constipated; that she had complained of headache, and generally of not feeling well, for something over a week, and had eaten next to nothing, and that on the evening of the 5th she began to complain of pain in her stomach and bowels, and became confined to the bed. When first seen, although there was undoubted tenderness in the right iliac region, there was no tympanites, and no rigidity of abdominal muscles, the absence of which symptoms, together with the history of headache and diarrhœa, completely led me astray in the diagnosis, and I stated to the parents that the diagnosis lay between simple fever and typhoid, with the chances decidedly in favor of the latter. I gave at this visit a febrile mixture of digitalis and nitre, and a camphor and opium pill, to be repeated once in four hours, and advised tepid sponging and milk diet. I saw her again on the evening of the 8th, and notwithstanding the patient had expressed herself as being much relieved by the opium, and had been able to get some sleep, I found a different state of things than I anticipated. Pulse 124, temperature 101, some pain in right iliac region. no further discharges from the bowels, but sufficient tenderness and rigidity of abdominal muscles in iliac region to warrant a change of diagnosis to circumscribed peritonitis. At this time she began to lie upon her back, with knees drawn up. I at once increased the amount of opium, giving two grains once in two hours, and also two drops Norwood's tinct. veratrum viride every two hours.

I will not detail the daily progress of the case, but give a general outline of the treatment pursued, as showing the good effects of opium in this disease. On the 11th inst. she was seen also by Dr. H. W. Buel, of this place, in consultation, who coincided with me, both in regard to diagnosis and treatment. From this time on to the 18th there was steady increase in the peritonitis until it became general, with great general distention and tenderness of whole abdomen. The veratrum was pushed from day to day, until she took 5 drops Norwood's tincture every two hours, and was able to take this amount for four consecutive days, keeping the pulse in frequency at from 85 to 95. On the 18th, without previous warning from nausea, she was taken with vomiting, and the veratrum was immediately discontinued. She had only two attacks of vomiting, and by resorting to the hypodermic use of morphia for a few times, was able to resume medication and nourishment by the mouth. The opium during this period was pushed from day to day, until she took 108 grains every twenty-four hours, and continued it in this large amount for four consecutive days. She also took during all this period, in which the disease was at its height, twelve ounces of rum each twenty-four hours. On the 18th she complained of a frequent desire to have a movement of the bowels, and this feeling continuing to annoy her, on the 19th she was given an enema of a pint of sweetened water, which was retained, but did not procure an evacuation. On the 20th, however, she had, spontaneously, two large fecal evacuations, which apparently gave her much relief. This day seemed to be the turning point in her favor, and from this time on to the 28th there was a gradual but steady convalescence. The opiates and stimulants were gradually withdrawn, and at date last mentioned, altogether discontinued. During three or four days at the height of the disease the insomnia and subsultus, and other symptoms of profound disturbance of the nervous system were so great that, in addition to the other remedies used, bromide of potassium in thirty-grain doses, repeated in from two to four hours, as seemed to be required, was resorted to, with much apparent advantage.

The following table shows the record of pulse, respiration and temperature, so far as a record was kept:—

June	7, P.M.,	pulse	134,	.....		temp.	104

"	28,	"	" 85,	"	20,	"	98 3/5

I will not take much time in comments upon the case, but simply call attention to a few of the most important features that seem of an unusual character.

In the first place, it certainly seems to have been, in this instance, an idiopathic or spontaneous affection, and not incidental to some other affection of the abdominal viscera.

Prof. Flint says, "it may occur from exposure to cold, but such cases are extremely rare." In this case, so far as could be determined, there was no other cause, and, in fact, no other evidences of a cold; but the parents stated that the girl had of late been gardening a good deal in the wet grass, and with insufficient clothing, and at or near the time menstruation should have occurred.

A peculiar feature also was the severe diarrhœa occurring for twelve hours at the very onset of the disease. It will be observed also that the case required an unusual amount of opium. Flint says "that, as a rule, both in his and in Prof. Clark's cases, from three to four grains of opium, repeated once in two hours, is sufficient. In this case, notwithstanding the patient was only a slight, fifteen-year old girl, she took, with apparent advantage, nine grains every two hours, for several consecutive days. It may be noted, also, that the doses of Norwood's tincture were exceptionally large and well borne, and I cannot help but think may have contributed to a favorable termination. During the whole three weeks of the illness, the patient took two quarts of milk in each twenty-four hours, and nothing else in the way of nourishment was attempted. She was frequently sponged with tepid water, at which she expressed great satisfaction, and during the worst of her sickness ice was constantly applied to the head, and seemed to help very much in controlling the extreme restlessness. In the twenty-one observations of the respirations it may be noted that, notwithstanding the large doses of opiates, the respirations were only at or below 12 on seven different occasions, and only once so low as 10. Flint says they should not be kept below 12. I think Prof. Clark advises that they be kept as low as 7 or 8.

One point more and I have done; Wunderliech's Thermometry says that, in peritonitis, "sub-normal temperatures are especially common, and always suspicious; death may follow them closely." In this case, on the 25th and 26th insts. the patient had a temperature of fully a degree below normal, but all of the other symptoms were those of convalescence, and no apparent harm came from the condition. The girl has made an uninterrupted and rather rapid convalescence, and is now able to walk about, and is fast regaining her strength.

A NEW METHOD OF TREATING UTERINE HEMORRHAGE.

BY M. R. BARKER, M.D.,
Of New Castle, Pa.

Physicians of experience know the extreme difficulty, sometimes, of arresting uterine hemorrhage, the uterus seeming to defy all remedies, and pouring forth the sanguineous fluid in spite of astringents, ergot, the tampon, etc., etc. The danger of uterine injections often causes physicians to hesitate long before resorting to them. I have been frequently placed in this dilemma, and although I have used injections successfully, yet I must admit that I always felt relieved when I found that the injection had not produced any dangerous consequences.

In view of the foregoing considerations I concluded to take a departure from the usual methods, as will be seen in the report of the following cases:—

Case 1.—During the latter part of October, 1881, I was called to see Mrs. H., who was suffering from severe uterine hemorrhage. I treated her with the ordinary remedies, but without producing any permanent benefit. The tampon, applied again and again, would, of course, produce temporary suspension of the flux, but upon its removal the hemorrhage would return as badly as ever. The constitutional effects resulting from the loss of so much blood becoming alarming, I concluded something must be done.

At my next visit I took my uterine applicator and placed upon it a spiral slide, leaving about three inches of the point uncovered. The point I wrapped with absorbent cotton in the same manner as for treating the uterine cavity for endometritis, with the exception that the end next the slide I made considerably thicker than the rest, and tied a thread around it, so as to withdraw the cotton when its purpose was accom-

plished. I then dipped the cotton into glycerine, and dusted it effectually with powdered persulphate of iron. I then exposed the os with a speculum, and passed my loaded applicator into the uterine cavity, and with the slide pushed off the cotton and left it. From that time my occupation in this case was gone. She made a rapid recovery.

Case 2.—March 30th, 1882, was called to see Mrs. W., who had been suffering with uterine hemorrhage for two months. I was of the opinion that she had had an abortion, but she denied it. She had been under the care of another physician, who had treated her with the usual remedies, the principal one being ergot. Her clothing and bed showed very plainly the severity of the hemorrhage. I also found several clots in the vagina. I used the persulphate in the same way as in Case No. 1. When leaving I requested her to let me know in a few days how she got along. In about a week I received a note from her saying that the hemorrhage ceased from the time of the application, and that there had been no return. I have met her several times since, and she was quite well.

Case 3.—Mrs. R. aborted about May 1st, 1882. I saw her June 29th. The attending physician had gone through the usual routine of remedies, administered internally, apparently without benefit. I immediately made an application of the persulphate of iron after the same manner as described in the former cases, and the result was an immediate arrest of the hemorrhage. She was in my office to-day, and as I had this article partly written, I asked her the particulars of her case. She said she had "wasted" for eight weeks, and that she had taken ergot nearly all of that time; and also that there was scarcely any discharge perceptible after I introduced the tent, and that there had been none since, beyond her periods.

It seems to me that this is a much more rational method of treating uterine hemorrhage than by either internal remedies or by injections. That it is much safer than by injections no one can deny, and I would not hesitate now to depend upon it, to the exclusion of all other remedies. This preparation of iron is used *ad libitum* in gynæcological surgery, without injury, and I am satisfied that it is equally as beneficial and harmless in ordinary uterine hemorrhage.

I am of the opinion that the benefit derived from this plan of treatment is not altogether from the styptic action of the iron, but that a portion of it arises from the intolerance of the uterus to any foreign substance in its cavity, the muscular fibres contracting forcibly to expel the intruder, and I cannot see why an ordinary case of uterine hemorrhage could not be treated successfully by non-medicated tents alone.

Hospital Reports.

BELLEVUE HOSPITAL MEDICAL COLLEGE, N. Y.

CLINIC BY AUSTIN FLINT, M.D.,

Professor of Pathology and Practical Medicine.

Pneumonia.

Gentlemen:—I will read the hospital record of this case, give the physical signs, and mention the therapeutical indications.

He is an Italian, 33 years of age, a laborer, and entered the hospital on the 27th of last month, six days ago. He cannot speak English, and the history is, therefore, somewhat imperfect. He walked to the ward on admission; the face was flushed; the temperature was about 102° F. It was impossible to learn whether he had any pain, but on physical examination the movements on the left side were found to be restricted. On percussion there was dullness over the lower portion of the left lung up to the angle of the scapula. In the infra-axillary region dullness extended up to the fifth rib. On auscultation the respiration was found to be purely bronchial over the lower portion of the left lung, shading off into broncho-vesicular as we ascended, where also a crepitant râle was heard. Over the lower portion a grazing friction was apparent; also bronchophony. Higher up we found increased vocal resonance. These were signs of pneumonia. The patient was put on milk diet, a little whisky, and five grains of quinine every six hours. The temperature was not sufficiently high to call for antiseptic treatment. At 5 P.M. it was 102.25. The expectoration was gelatinous and rusty.

On the 28th, temperature 101°, the respirations 20 per minute, which was considerably lower than before. There was vesiculo-tympanitic resonance over the unaffected portion of lung on the same side. On the 31st, there was a subcrepitant râle, indicating resolution.

Here we have apparently a very good typical case of pneumonia, which has pursued its course without much medicinal interference. The patient has had a little stimulant, on the general principle that patients admitted into Bellevue Hospital have usually been addicted to the use of alcoholic stimulants to some extent; and he has had five grains of quinine three times a day. The disease, in fact, has been allowed to pursue its own course, and the patient may now consider himself convalescent. It is a self-limited disease.

Resolution is now nearly complete, as is indicated by the disappearance of the abnormal physical signs before referred to, and you would hardly be able to tell now, by an examination of the lung, that this was the affected side. Here, then, is an instance of a very rapid resolution, and as you meet with cases in private practice, bear in mind that the period of the resolving stage of

pneumonia varies very much in different cases. Sometimes it is astonishing with what rapidity the absorption of so much matter takes place. Recollect that this patient must have had at least a pound of exudation in the lower lobe of the left lung, and now, within three or four days, it has pretty much all gone. In other cases it will require many days, and sometimes even many weeks, before it disappears. In some rare cases resolution is so slow that you will conclude you have something more than a pneumonia; that you have a phthisical exudation instead of a pneumonia. But after a while resolution becomes finally accomplished.

Renal Disease.

I shall now show you a case of general dropsy depending upon renal disease. I refer to this case now, so that, in some regards, you may make the contrast between two classes of cases. Here is the patient, and you see he presents a pallid aspect. He is anæmic, as is apparent when you look at him. There is some tumefaction of the face, but not, I believe, as marked as it was a few days ago. When I saw him day before yesterday I am quite sure he had more œdema here than he has to-day. And you see he lies in bed without giving any evidence of embarrassment of breathing. Now take the points of contrast between cases of cardiac dropsy and this one. In the first there is usually more or less lividity of lips and face. You may have the same amount of œdema, or more, but instead of this pallor we have a dusky or well marked livid hue, since almost invariably, perhaps you may say invariably, there is more or less evidence of embarrassed respiration. Here are points of contrast which pertain to the general aspect of the patient in cases of cardiac dropsy and cases of dropsy from renal disease.

Let us see what the history tells us, and then we will try and determine what probable variety of renal disease is present in this case.

He is thirty-five years of age, a native of Ireland, a stone cutter. Admitted on the 27th of last month. He had always been in good health, a hard working man, up to April last, when he began to have sciatica, and this annoyed him more or less until the latter part of July, when he noticed his penis was considerably swollen. He was in the habit of pricking the skin with a needle and letting the water run off. He must have had some œdema of the feet, but it was not so marked as to cause him to notice it much; could not have given him much inconvenience. Soon after this the feet, the legs, and the scrotum began to swell, and he noticed puffiness of the face. He continued to work until in July. Just previous to this time he noticed that he began to become considerably enlarged. He was often passing a large quantity of water, often getting up several times in the night. For about three months past he has kept abed most of the time. The dropsy increased. Five weeks ago he began to be affected with shortness of breath. He never had rheumatism, and none of the eruptive fevers since childhood. Was in the habit of using intoxicating liquors steadily, seldom, however, becoming intoxicated. He suffered from shortness of breath, loss of appetite, loss of strength, presented a cachectic appearance, felt water-logged, being œdematous in all parts of the body except the face; the abdomen was much distended, there being evidence of fluid on palpation; also signs of fluid in both pleural cavities. He was placed upon the following remedy: two drachms of the infusion of digitalis; two drachms of the liquor ammoniæ acetatis; one drachm of the spirits of nitre, taken every two hours, as a diuretic.

The urine was amber colored, alkaline, the specific gravity 1.014; contained forty per cent. of albumen. There were found large and small hyaline, and granular and fatty casts. After admission, his respiration becoming labored, he was aspirated, seventy ounces of clear serous fluid being withdrawn. Last night he received a dose of Epsom salts, which produced a free, watery stool. He afterward received other diuretics, as the compound jalap powder, which seemed to increase the quantity of urine. It is noted that on yesterday he was not much improved. He was weak. The fluid on the left side of the chest extended up to the fourth dorsal vertebra. The specific gravity of the urine was then 1.018, and contained eighty per cent. of albumen. A diuretic was given.

The liquid in the chest in this case was dropsical. It was bilateral. As a rule, in hydrothorax not associated with general dropsy, the accumulation of the fluid is much greater in one side than in the other. I do not know that there is any rule for determining which side is likely to contain the most of the effusion, but it is a fact that we sometimes meet with cases of hydrothorax in which one side of the chest is almost filled with liquid, while there may be but a moderate amount upon the other side. Under those circumstances it is perfectly proper to aspirate, and it will be found that aspiration occasions no inconvenience, for the reason that the lung expands without difficulty, there being no lymph to restrain it, and it is comparatively a trifling matter to withdraw all the liquid at once. This patient was relieved by that operation. He now shows, as you see, considerable œdema, more upon one side than upon the other. There is considerable œdema of the lower limbs. He has the same marked pallor of the skin mentioned in the history, indicating anæmia. The belly contains liquid, but so far as we may judge, not in proportion to the general dropsy. We obtain signs of fluid there very distinctly. To determine that, one of two ways may be employed. First, place one hand on some part of the abdomen, and with the other percuss on the opposite part—diametrical percussion, as it is sometimes called—and feel a sense of fluctuation; or, second, we may practice what is sometimes called peripheral percussion. I will not detain you by explaining the physical signs of fluid in the pleural cavity, as I feel quite sure you know them already.

From this history we may assume at once that the patient has some chronic affection of the kidneys. It evidently dates back as far as April, although he continued at work several months afterward.

Now comes the question, what is the probable variety of renal disease which exists in this case? Is it that variety which is represented by the

large white kidney? Is it the waxy kidney? Is it the cirrhotic or contracted kidney?

"The large white kidney." Yes, I present the case as one of the large white kidney. Taking all things together, I think we have the signs which are distinctive of that variety, and that is the reason I present the case to you. Dropsy is generally a very common symptom of this form of renal disease, and anæmia is a very prominent symptom. Now, we may explain those two circumstances pertaining to this form in this way: there is a great loss of albumen going on. First, we here lost forty per cent., then eighty per cent. We can understand how that impoverishes the blood, how it reduces the number of red blood corpuscles, which are dependent in some way or other upon the presence of albumen. We can understand how the blood, diminished in density, undergoes exudation more readily; so we can explain the anæmia and the dropsy in a great measure by the loss of albumen. Some years ago I studied, analytically, a number of cases of Bright's disease, and that was one of the points that I raised in my mind, and I found that as a rule the amount of dropsy and the evidence of anæmia was in proportion to the amount of albumen found in the urine. You can lay that down as a principle.

Enough urine is being eliminated, you say, so that he is not likely to manifest symptoms of uræmia, unless we consider the loss of appetite such a symptom; but that is a symptom accompanying so many conditions. In this case we need not impute that simply to the retention of urea.

Now, with regard to the therapeutical indications. It is an object to get rid of this water, and yet that is not so much an object as to justify us in using such vigorous measures in effecting it as to impair the digestion, the assimilation; for, although we would like to see his limbs assume their normal size, yet that condition does not of itself produce any important ulterior or immediate consequences. Diuretics in cases like this should certainly be tried, but they are very likely to prove ineffectual. The dropsy is diminished more certainly, more promptly, by the use of hydragogue cathartics. Here is a practical point. A hydragogue cathartic which acts pretty briskly and within a tolerably short period will not impair the patient's strength much, if at all. Resort to these from time to time, but do not follow them up too constantly. In the meantime try to build up the patient by tonic remedies. The muriated tincture of iron is one of the best tonics. Give the patient as nutritious a diet as he is capable of taking; a little alcoholic stimulant, in some form, if it be found to agree with him. Those are the measures of treatment. Do not keep working on the bowels every day and all the time, because that measure of trying to remedy the dropsy conflicts with the still more important measure of improving the general condition of the patient. Take another case, where the object is a different one, though the measures to be employed are the same; a case of uræmia; the object being to eliminate the urea, due, for instance, to contracted kidney, in which there is, perhaps, no dropsy. You will be thinking in such a case that it is important for this patient that the urea should not be retained, and so you may want to be prescribing hydragogues and diuretics all the time, and you may do harm by too great a pertinacity in the use of these measures. Be guided by the indications; be guided by the quantity of urine and the specific gravity, and by the symptoms which denote or do not denote the existence of uræmia. The quantity of the urine and its specific gravity will enable you to judge pretty fairly whether the patient is eliminating enough to be safe. If there be present no symptoms of uræmia, you have an additional proof that there is no immediate indication for the use of potential measures to get rid of urea in other directions than the kidneys.

Œdema Glottidis.

One of the cases, gentlemen, which I intended to present to you to-day cannot be presented, for the reason that he is no longer in this world. But it is a very instructive case, and I propose to occupy a few moments in reading the history of it. It is the case in which there occurred in connection with suppurative inflammation of the neck externally, œdema glottidis. I did not make a visit to the hospital yesterday, but the day before I found this patient here, and there had occurred œdema of the glottis in one side. It was determined by means of a digital examination. Embarrassment of the respiration was so great at one time that it was thought it would become necessary to perform tracheotomy. However, the symptoms were relieved, and he was entirely relieved day before yesterday. I wanted to present the patient with reference to bringing before you the evidence of œdema of the glottis and practical points connected with it. I learned this morning that the patient died. I will read the history.

He was a man thirty-five years of age, a native of Ireland, admitted into the hospital on the 7th of last month. About two weeks before he fell and struck on the back of the head, receiving a slight wound, which healed readily. He felt no inconvenience until about a week afterward. There was a stiffness of the neck and a swelling behind the ear, the latter steadily increasing. There was inability to open the mouth wide. On admission there was swelling on the left side of the neck, extending downward and backward from the angle of the jaw and also behind the ear. It was firm, not very tender, and was thought to be an enlargement of the parotid gland. Inside the fauces were apparently normal, but it was impossible to get his mouth open wide enough to see the throat well. He gave no history of syphilis, and no evidences of that disease were found. The swelling was painted with iodine, and the iodide of potassium and bichloride of mercury were given internally. The skin becoming tender, the iodine was discontinued and the oleate of mercury used. Some œdema of the skin occurred, and there seemed to be deep-seated pus, which became quite evident after applying poultices. Early in the morning of day before yesterday the orderly reported that the patient was dying. He was found greatly cyanosed; threw himself about, struggling violently for breath. The difficulty seemed to be most with inspiration. On pass-

ing the finger back into the fauces, a firm, smooth, rounded tumor was felt on the left side. (Please recollect that important practical point in making a positive diagnosis.) An incision was made about four inches below the ear, at the lower portion of the deep-seated fluctuation, and pus was evacuated to the amount of about two ounces and a half. This relieved the immediate symptoms of pressure, and he breathed after that much more easily. During the next day there was some embarrassment of respiration, but he breathed comparatively well. Toward evening, however, the respiration became more embarrassed, and the question of performing tracheotomy was raised. It did not seem then to be necessary. About two o'clock in the morning he was reported to be dying. He was lying apparently dead; pale, no evidence of congestion; respiration apparently had ceased; no pulse, a faint heart beat. Tracheotomy was performed; the wound was kept open with the forceps; artificial respiration was employed. After five minutes he began to breathe with great difficulty, of himself, and the blood returned to the face. The tracheotomy tube was then procured, with which to keep open the wound. He became delirious, threw himself about so violently as to require three or four men to hold him. He never became conscious afterward. This continued about an hour. A hypodermic injection of morphia quieted him somewhat. He breathed freely through the tube, but the cerebral symptoms of carbonic acid poisoning never disappeared. He was unable to swallow, and was fed by passing a catheter down the throat and per rectum. He improved somewhat; the pulse became better, he breathed freely and easily, but about 2 P. M. there were signs of irritation of the cord; the neck was drawn back, as in cerebro-spinal meningitis, there was twitching of the muscles of the face and arms, and from that on his condition became worse, the heart more feeble, less regular, and he died this morning about 4 o'clock, apparently of exhaustion.

This is a very interesting and instructive case. While speaking on the subject of œdema of the glottis, in the didactic course, I endeavored to impress the point that there is liability to a sudden increase of the œdema, which may destroy life very quickly indeed; and that is a very important fact to bear in mind. Although in this case the patient was in the hospital, yet before tracheotomy could be performed, there being no delay, the respiration had ceased. Still, in this instance, by employing artificial respiration, life was restored, and the man finally died, not because the operation of tracheotomy was unsuccessful, but from the effects of the carbonic acid poisoning, which had reached so great a degree before respiration was reëstablished.

The Laryngeal Complications of Consumption.

Dr. James H. Williamson contributes a valuable paper on this subject to the *British Medical Journal*. The existence of laryngeal complications in a case of phthisis indicates that the case has become, even if it were not at first, a constitutional one; and the new malady, like the cerebral and intestinal complications which also occur, is one of its local expressions. Men are much more subject to the laryngeal complications than women. Out of five hundred cases of consumption which he observed consecutively, no more than thirty-four complained of laryngeal trouble, equal to 6.8 per cent. It must, however, be remembered that this complication is mostly found in advanced cases; taking, therefore, none but fatal cases, he found that in one hundred and six there were 25, equal to 23.6 per cent., and Louis, in his post-mortems, found some portion of the tract ulcerated in 33.2 per cent. Symptoms are not always present, but when they are, they will generally furnish indications as to what part of the tract is involved. When there is heat and pricking low down in the throat, with dryness and dysphagia, we suspect inflammation or superficial abrasions about the epiglottis, or in the folds of mucous membrane running between it and the tops of the arytenoid cartilages. Great supra-thyroid pain, with burning and marked dysphagia, and with pain shooting up to one ear, will point to acute inflammation or deep ulceration of such parts. The dysphagia is greatest when the angles of the epiglottis and the aryteno-epiglottidean folds are involved. Pricking in the box of the larynx, with hoarseness or intermitting aphonia and semi-laryngeal cough, most often depend upon thickening or inflammation of one or both cords. Supra-sternal pain, constriction, or perhaps spasmodic dyspnœa, generally none of them very positive, will give hints of inflamed spots, thickened patches or ulcers of the trachea. In his experience, ulceration never exists in the larynx unless the pulmonary phthisis has reached the stage of excavation. In making a diagnosis the laryngoscope will eliminate hysteria and paralysis of the vocal cords. If chronic laryngitis coexists with pulmonary phthisis it is proper to associate the two pathologically. In syphilis the larynx is affected in only a very small proportion of cases; according to Mr. E. C. Morgan only 4.8 per cent. Primary laryngeal cancer is very rare. If the general and local signs are taken together, there should not be any insuperable difficulty in diagnosing between syphilitic, cancerous, and tubercular disease of the larnyx. So far as the ultimate prognosis is concerned, it is simplified by the appearance of the laryngeal complications, for they are a sign that the patient's tether of life is not a long one, even for consumption. The treatment must be aimed at their arrest, which will be accomplished by sedatives and rest. A sedative night draught should

be resorted to from time to time; thirty minims of the solution of hydrochlorate of morphia for a few consecutive nights will give good results and do no harm. Where dysphagia is prominent, ice to suck before medicine and food will be of service and the night medicine may be given hypodermically. Small doses of morphia may be given during the day. Outwardly, poultices or spongio-piline, wrung out of hot water and well sprinkled with laudanum, must be applied over the affected sore. A few drops of Battey's solution in the ear have often given relief. Inhalations of steam, medicated with a mixture of chloroform, compound tincture of benzoin, and juice of hemlock, are of service. This sedative treatment must be continued for a long time. In latent or chronic cases over treatment will excite, and it is well to do but little. If accessible, paint the surface once, not oftener than twice, a week with nitrate of silver solution (twenty-five grains to the ounce). When out of reach use the same solution by means of an atomizer (one to two grains to the ounce). The stimulant and alterative action of the silver salt may be varied with the stimulant and astringent action of sulphate of copper (fifteen grains to the ounce). Externally, counter irritation must be used. Great attention must be paid to diet.

Experimental Biological Research.

The *British Medical Journal* furnishes the following interesting statistics. It says the reports of Mr. Busk and Dr. Thornley Stoker, showing the number of experiments performed on living animals under the Act for Regulating Experiments on Animals, during the year 1881, have been published as a Parliamentary paper. Mr. Busk reports that the total number of experiments performed during the year in England and Scotland, by the thirty eight licentiates, was about 270. Of these, 59 were performed under the restrictions of the license alone; 90 under certificates permitting experiments (with anæsthetics) in illustration of lectures; 29 under special certificates for experiments without anæsthetics; 92 under certificates dispensing with the obligation to kill the animal before recovery from anæsthetics; and one under a certificate permitting experiments on "cats, dogs, horses, mules, or asses." The only experiments in which it is likely that any appreciable suffering would be caused, are among those performed under the certificates of the last three descriptions. In all the experiments under the first and third of these heads the only operation consisted either in simple inoculation with a morbid virus, or in its introduction by hypodermic injection; the proceeding in either case being no more painful than the prick of a lancet or needle. Of the experiments under the second head, 68 also consisted in simple inoculation with a morbid virus, or the introduction by hypodermic injection of various substances of a poisonous or medicinal character. In most of the inoculation experiments no effect was apparently produced; while in those in which the inoculation took effect, either death speedily ensued or the animal was killed after a very brief interval. This was the result in about twenty or twenty-five cases, among which are included eight (seven mice and one frog) caused by poison in the prosecution of a recent criminal investigation (the Lamson case). In the other experiments of different kinds performed under the certificates dispensing with the obligation to kill before recovery from anæsthetics, the only pain caused would be that attending the healing of a wound and the necessary confinement, or in some cases produced by the action of drugs administered. The number of cases in which trifling suffering of this kind was caused might be ten or twelve. As in the experiments performed under the license alone, or under certificate for lecture illustrations, the animals are placed and kept in a state of anæsthesia, no pain need be inflicted; and Mr. Busk has every reason to be assured, as regards the due administration of anæsthetics, that the provisions of the Act are fully carried out. Of this he has on several occasions had an opportunity of satisfying himself from personal observation. He therefore states with confidence that, during the past year, no case has arisen in which it was found necessary to inflict pain, except of the most trivial nature, in the prosecution of scientific inquiry. Dr. Stoker's report for Ireland is of a similarly satisfactory character. He reports that under the licenses twenty-seven experiments were performed, "all of a highly useful character, being designed to elucidate the actions of drugs, or to throw light on questions of surgical and medical pathology." Dr. Stoker is of opinion that in all cases those persons qualified to experiment under the Act have conformed to its directions, and have observed all possible humanity in their investigations, and that no appreciable suffering has been caused to the creatures experimented on.

Neuro-dynamic Medicine.

Dr. B. O. Kinnear contributes an interesting and valuable article to the Boston *Medical and Surgical Journal*, on Dr. Chapman's system of neuro-dynamic medicine. This system consists in the theory that ice in disease, used properly, in rubber bags of the right length and width, over the spinal and sympathetic centres, dilates the arterioles controlled by such centres, and arrests at the same time hypersecretion from the glandular system, checks spasmodic and irregular muscular movements of voluntary and involuntary muscles, and arrests hypernutrition by its sedative action upon trophic centres. Heat used likewise acts in an exactly opposite manner. He has been able to relieve the pain of neuralgia, in some cases by ice and others by heat, as quickly and in many instances more rapidly than by hypodermic injections of morphia. Besides the swift relief afforded, this method of treatment has the additional advantages of not producing nausea, vomiting, headache or any other bad symptoms. In a case of agonizing pain from passage of gall stones, ice was applied over dorso lumbar region, and in *three minutes* all pain and tenderness had disappeared, whereas in previous attacks morphia had been wholly inadequate to relieve the suffering. In wind colic, applied over the same region, it will give immediate relief. It will relieve bilious attacks and sick

headache when applied over same region. In acute diarrhœa it will check the bowels, allay vomiting if it exists, and in the severer forms will restore warmth to cold and cramped extremities. In the vomiting of pregnancy, carefully used, it promises much. In gastritis, in simple leucorrhœa, and in constipation, he has used it advantageously. He has derived excellent results in hysteria from the effect of ice in subduing the hyperæmia of the sympathetic ganglia, and those spinal centres which give rise to the muscular spasm when unduly excited, as in these cases. In sleeplessness due to excessive use of the brain. from almost any cause, ice applied low down (dorso-lumbar region) will produce sleep by dilating the arterioles of the lower body, thus withdrawing from the cerebral circulation its excessive supply, the cause of the sleeplessness. When the ice is not sufficient, thus applied, to have the desired effect, a double-columned hot water bag may be used over the sympathetic ganglia of the cilio spinal region of Chapman, or, in other words, the cervico-dorsal vertebræ, and will assist, by stimulating these ganglia, to a hyperaction, causing thereby a contraction of the blood vessels of the brain. He used it with benefit in one case of asthma.

Dr. Kinnear, in conclusion, says: "I would again suggest to those of my medical confrères who may decide to try this method, not to do so without a careful attention to those *dangers* with which a careless or ignorant application will certainly bring them face to face. Upon these *dangers* Dr. Chapman gives very clear and minute directions and cautions."

Venesection in Heart Disease.

In the *Lancet*, Dr. Bedford Fenwick, in the course of an interesting article on this subject, says that his attention was first called to the value of venesection in heart disease by a mere accident. A young man was admitted into the hospital with mitral stenosis and aortic regurgitation. His condition became gradually more and more critical until he became drowsy, almost comatose, and his death was hourly looked for. When in this condition he threw up his arm, and striking his nose violently, it began to bleed very freely. Attention being called to another patient, his nose was allowed to bleed, thinking that it would soon stop. He lost some twelve or fourteen ounces of blood, and when again examined was found perfectly conscious, breathing quietly, and calmly said that he felt much better. His improvement was uninterrupted, and in a few days he returned home. Loss of blood is a common cause of fatty degeneration, therefore it would not be wise to bleed where we have or fear fatty degeneration.

Dr. Fenwick only uses leeches or cupping to remove blood directly from the cardiac region in cases where stenosis exists. He imagines that we obtain thereby more certain and more rapid results with a more accurate loss of blood than when venesection from the arm is resorted to. Still this is a matter of such great practical importance to the patient's welfare and to our own success, that he feels bound to state distinctly some reasons for his judgment: 1. The patient and the patient's friends usually object less when leeching or cupping is suggested, than when "bleeding" is proposed, and they are less alarmed at a local application to the seat of disease than at the procedure necessary to open a vein and keep it bleeding. 2. The quantity of blood to be abstracted can be more accurately measured and controlled, and is generally much more easily obtained, in cases of advanced stenosis, by local than by brachial venesection. 3. Even as, like all practical men, he gives a hypodermic injection of morphia at the seat of pain, although he cannot explain why its insertion there should give so much greater and more rapid relief than when introduced into the same blood at a distance, so he cannot explain why a little blood removed from the cardiac region should afford greater and quicker relief than is derived by the abstraction of even a somewhat larger quantity from the arm. He does the former and leaves the latter undone in these cases, because he is convinced of the great practical truth that thereby greater good is gained.

He has been astonished to find how drugs which had been given for days or weeks without apparent benefit, as soon as even a little blood has been removed, seem at once to assert their power again. Next, with regard to acute pericarditis and endocarditis, he has not had the opportunity of using venesection in many such cases, but where he has done so he has invariably bled by cupping the cardiac region, and always with good result—so successfully, indeed, as to make him believe that if this measure be taken at the onset of the disease it will very often, if not always, cut the attack short, or at least greatly mitigate its severity."

Finally, with regard to pain, more or less severe and more or less persistent in the cardiac region, he has found nothing give such rapid and complete relief as local abstraction of blood. In conclusion, he summarizes thus:—

1. In cases of valvular stenosis, if dyspnœa, or pain, or urgent symptoms be present, bleeding is generally useful; that it appears to be better to bleed often, if necessary, but to take only a small quantity each time, and this by means of leeches or the cupping glass, direct from the cardiac region.

2. In cases of valvular incompetency, if urgent dyspnœa or cyanosis or stupor be present, it appears best to bleed freely from the arm, to about sixteen or twenty ounces, if necessary, and if possible once for all.

3. In cases of acute pericarditis and endocarditis the attack may possibly be cut short by freely cupping the cardiac region at once.

4. In cases of cardialgia, without any evident cause, leeching or cupping over the heart's area will probably give relief.

Reviews and Book Notices.

BOOK NOTICES.

The Humboldt Library of Popular Science Literature. J. Fitzgerald & Co., New York City.

The publishers issue standard short essays on various scientific subjects, at the nominal rate of

15 cents each. The books are well printed, on good paper and in clear type. Some of these essays which might interest physicians are, "Mind and Body," by Alexander Bain; "Longevity," by John Gardner; "Lessons in Electricity," by John Tyndall; "Hereditary Traits," by Richard A. Proctor; "Oriental Religions," by John Caird, etc. The address of the publisher is 30 Lafayette Place, and any of these are mailed to the purchaser who remits 15 cents.

Labor Among Primitive Peoples; Showing the Development of the Obstetric Science of To-day, from the Natural and Instinctive Customs of all Races, Civilized and Savage, Past and Present. By Geo. J. Engelmann, A.M., M.D. St. Louis: J. H. Chambers & Co. pp. 202. Cloth. 8vo. Price $2.00.

Dr. Engelmann shows, in this work, that he is both a finished obstetrician and an ethnologist of close and extensive reading. Its pages are full of curious information, and the practical lessons drawn from a study of the customs connected with lying-in and birth in different ages and nations, are deserving the attention of every scientific accoucheur. One of the most unexpected results discovered is that observation and instinct have taught many savage people methods of the management of labor which, as the author remarks, "that only within the last few years are the most alert of our obstetricians in a position to compare with them."

It is especially in "massage and expression" that this is true, and the extent to which these plans of facilitating labor are used by primitive people testifies to their value.

The volume is illustrated with fifty-six woodcuts and a photograph, showing scenes of labor in ancient and modern times, the position of the patient, and the assistance rendered.

Lacerations of the Female Perineum and Vesico-vaginal Fistula; their History and Treatment. By D. Hayes Agnew, M.D. 75 Illustrations. pp. 141. Philadelphia: P. Blakiston, Son & Co. Paper 75 cents.

Of the two subjects here treated of, the first occupies fifty-six pages, the second, the remainder of the volume. Much of the space is taken up with descriptions of instruments and minute directions for the operations. Upon a strict observance of these minutiæ the success of the surgeon will depend. Dr. Agnew's statistics are good. He tells us that he has operated for vesico-vaginal fistula about sixty times, with three deaths, all doubtless due to a hospital atmosphere, and with not more than four or five failures.

Dr. Agnew's views about perineal lacerations are important. He does not divide the sphincter, and does not use the quilled suture. He cures the laceration of the perineum and recto-vaginal septum at a single operation, and by a peculiar method of inserting the first (interrupted) suture he does away with the necessity for a series of stitches to close the septum independent of those used for the closure of the perineum.

Mental Pathology and Therapeutics. By W. Griesinger, M.D. Translated from the German by C. Lockhart Robinson and James Rutherford, M.D. New York: Wm. Wood & Co. 1882. (Wood's Library of Standard Medical Authors).

Griesinger belonged to the last generation of German psychologists, and this translation of his treatise was published in England fifteen years ago. Since then psychiatry has taken a different direction, and although no one can fail to learn something from a perusal of Griesinger's half metaphysical doctrines, it would be a grave error to suppose that they are now current. Mental pathology has received vast accessions from histology, which Griesinger knew nothing about. The basis of the study of mind and of the distinctions of its morbid states is now seen to be, in the most direct sense, the body. The author was, however, an acute observer, and remarkably well acquainted with the literature of his specialty.

Cerebral Hyperæmia; Does It Exist? A Consideration of some Views of Dr. William A. Hammond. By C. F. Buckley, B.A., M.D. New York: G. P. Putnam's Sons. 1882. 12mo. Cloth. pp. 129. Price $1.00.

Dr. Buckley, who was at one time superintendent of an English Asylum, makes a vigorous onslaught on Dr. Hammond's theories about cerebral hyperæmia and anæmia, with which the profession is familiar. Many of the critic's objections are well founded, and if Dr. Hammond still upholds those theories, he will have some difficulty in meeting the objections. The tone of the writer is at times too controversial, inclining to personalities, which rather injures the weight of what he says.

Handbook of Ophthalmic Practice. By Charles Higgins, M.D., F.R.C.S. Second Edition. Revised. Philadelphia: P. Blakiston, Son & Co. 1882. 12mo. pp. 116. Cloth. 50 cents.

This is a very brief description of the principal diseases and injuries of the eye; too brief for most purposes, but, perhaps, of some advantage to the student in running over the subject in view of an examination. Its brevity is the only objection we have to it. Otherwise it is well written and the doctrines sound.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE NEGLECT OF THE STUDY OF PURE SCIENCE IN AMERICA.

The word *practical* is in undeserved honor among us. It is supposed to be the highest compliment that we can pay a book or a man to say that it or he is "eminently practical." The tradesmen have caught it, and we see in the streets the signs of "practical bootmaker," "practical carpenter," as if to draw a distinction against others in their callings who ply their trade in a theoretical manner only.

This is a great mistake. The practical man, practical pursuits, practical purposes, mean such as are directed to the accomplishment of known and narrow aims. Were all men practical we should fall into a condition of Chinese fossilization. Our salvation lies in the contemned unpractical men.

Nowhere is this more obvious than in science. Directed to solely practical ends, science makes but little progress. Those who have given it its greatest impulses are they who pursue it for its own sake; they who are seekers after its abstract truths, without caring whether these can be applied to the everyday wants of life or not.

Nor is the science of medicine any exception to this. Those who most deserve our thanks for discoveries in it have not been those whose first ambition was to get a "big practice," but rather whose enthusiasm was for knowledge more than for fame or money.

But, alas! How few of these there are anywhere in the world! Least of all do they flourish among us. And when a young man is willing to devote himself to this noble but arduous path, how little encouragement he has from any quarter!

In Europe there are foundations and fellowships, chairs in the universities and government aid for men of promise who wish to study abstract science. But where are any such helping hands among us?

The meagre appropriation of late years granted by Congress to the National Board of Health is now withdrawn. The Medical Colleges give out their chairs on other grounds than the love of science. Fellowships and foundations are practically unknown. In fact, there is nowhere any provision made to aid the student who would spend his whole time in the search for abstract truth.

The result of this is sure to be unfavorable. It lowers the mark for endeavor and depreciates the standard of thought. More and more is medicine looked upon as a mere trade, as a means of getting a living and making money. Even now, those who still retain some scruples about reducing it to the ordinary ethics of a trade-union are looked upon as behind the times, or eccentric.

Hospital positions are manipulated to increase private practice; books and essays are run through the press, not to instruct others, but as baits to fish for patients; novel instruments and operations are brought forward, not for their intrinsic value, but that the inventor may get ahead in the world. Rule out of our literature all that is written from such motives, and how little would remain?

The remedy for this is to uphold the supreme importance of the pursuit of abstract science, of

those studies which have no practical aim, but seek the truth alone. Award to these dignity and the highest place, which is theirs of right, and we shall do much toward infusing a nobler spirit in all who pursue our science.

REST IN TREATMENT OF HEART DISEASE.

By this we mean not positive, but comparative rest; neither do we refer to acute inflammatory affections of the heart, wherein, from the very gravity of the disease, confinement to bed and consequent rest become necessarily assured. We are thinking of those cases of heart exhaustion, so to speak, of individuals whose general health and tonicity is much run down, from overwork or abuse, and in whom the heart shares in this general vitiation. Possibly the organ is not in itself diseased; its organic integrity may be perfect, but its muscular walls may be flabby and weak, ready to yield to, or, more properly, unable to resist, any great strain. If, when in this condition, the man resorts to any violent muscular exercise, or subjects himself to the influence of violent physical emotions, this weak heart may become mechanically distended, in its efforts to perform the extra labor demanded of it. Or it may be that dilatation has already taken place to some extent; then does it become important to allow the organ time for the development of the beneficent hypertrophy that will do so much to preserve its integrity. By rest, we mean to advise your patients who are threatened with or already have dilatation of the heart to do everything slowly, to perform every act of life deliberately, and to avoid, as far as possible, all occasions calculated to excite the passions or emotions. We must ever remember what a delicate machine the heart is, and how easily it can become deranged, and realizing this, must consider how much more care this organ requires when it is already diseased. We must, under such circumstances, walk slowly, think slowly, eat slowly, in a word, do everything slowly. It is not well, and we do not recommend the carrying of this advice to the verge of laziness; but what we do mean is, that while it is well for all (either sound or diseased) to avoid hurry, it is ten times more important, aye, absolutely imperative, for the man with a weak or diseased heart.

Notes and Comments.

Resection of the Pylorus.

In a correspondence to the *Wiener Med. Woch.*, Dr. Anton Wölfler, in Vienna, mentions, in regard to the results of the resection of a carcinomatous pylorus, that the woman on whom he performed this dangerous operation one year ago was living in a "splendidly nourished" condition; that all subjective complaints have ceased, and that the repeated and careful examinations have proven to an undeniable certainty that no recurrence of the malignant growth, either in the stomach or in the neighboring lymphatic glands had taken place. He also tells us that the second patient on whom Billroth operated for the same cause, October 29, 1881, was "perfectly well, looked strong, and is happy to be able to return to her usual occupation without any disturbance or impediment whatever."

These are results that should stimulate us to new exertions; the operation is not alone justified, but in proper cases even strongly demanded. "May it," concludes Wölfler, in his letter, "succeed right frequently, to the benefit of the human race and to the honor of the medical profession."

American Dyspepsia.

In the Boston *Medical and Surgical Journal*, Dr. James H. Robbins takes the ground that the prevalence of dyspepsia among us is due less to improper food, badly prepared, to haste in eating, or to excessive eating, than to the fact that we nearly all are the possessors, either by inheritance or acquirement, of imperfect nervous organizations that are consequently unable to lend their aid to digestion as they should; for this reason but few of us are able to digest enough food for our bodily repair; hence we experience the sensation of having over-eaten, when in reality we have not had enough. The author says:—

"Such causes operate with special power upon us of the present generation of the Anglo-Saxon race, whose ancestors came to this country several generations ago, for the reason that from these ancestors we inherit nervous systems of impaired vigor. Our parents and grandparents were so strenuously engaged in an arduous, ambitious, and competitive endeavor, amid the

rapidly changing conditions of life in a new country, to secure competency and respectable social position, that they expended, to a great degree, their own vital powers, and have accordingly transmitted to their children delicate and neurotic constitutions. If it is granted that we inherit a diminished vitality, it is easy to see how ingeniously the pressure, the wear and tear, the strain, the excitement, the hurry and worry incident to this breathless, bustling life of ours, affect the nervous system. It is also evident that impairment of digestion and mal-nutrition must be the certain result of such a condition of things."

This deterioration of the nervous system is fostered and increased by our faulty methods of raising children and our own erroneous style of living when we reach maturity. The evident remedy is to be found in an elevation of the tone of the nervous system. Whether this theory be true or not, it is a very charming one, and would certainly seem to account for much of the dyspepsia that renders so many persons miserable.

Temperature in Cardiac Disease.

The *Lancet* says a monograph upon the above subject has recently been published by M. Sabatier. His researches embrace the determination of the local temperature of the præcordia, as contrasted with the axillary temperature. He states the normal temperature of the præcordial region as 36.1° C. (about 97° F.), liable, however, to variations in different subjects. In pericarditis the axillary temperature is much raised in acute cases, but not influenced in chronic and subacute cases. The præcordial temperature is increased in acute and subacute pericarditis, but where there is much fever, as in acute rheumatism, the præcordial temperature is lower than the axillary. When the local inflammatory process is very intense this difference may be reversed. When right-sided pleurisy coincides with pericarditis, local thermometry indicates the relative intensity of the two inflammatory processes. During endo-pericarditis the local temperature does not subside so soon as the general. In endocarditis there is no local rise in temperature, a point of distinction from pericarditis. In cardiac hypertrophy the præcordial temperature is the same as, and sometimes lower than, that of the opposite side. Vesication applied to the præcordia keeps the temperature at a high level for several days. Numerous tracings are given, and, although the subject is limited, and, perhaps, hardly sufficiently fruitful, considering the labor expended upon it, it is the first contribution to local cardiac thermometry that has been made. The author believes that the method is a valuable aid to diagnosis, and that the local temperature of the cardiac region should always be estimated. It is of most importance at the close of the acute period, when the axillary temperature has become normal.

Peculiar Attacks in a Case of Locomotor Ataxia.

Drs. Raymond and Oulmount observed peculiar attacks in a patient suffering from tabes. Dr. Bernhardt gives us, in the *Centrlb. f. d. Med. Wis.* 9, 1882, p. 160, the following description:—

The patient awakened suddenly, usually in the night, with a violent desire to micturate, but passed a few drops only; a most intense pain seemed to tear his urethra apart. This paroxysm lasted from one to two minutes and returned every fifteen to thirty minutes. The duration of the whole seizure was generally from ten to twelve hours; toward the close, the poor sufferer passed a few drops of pure blood; the attacks then ceased, but nearly the whole of the following day the urine was somewhat bloody.

Such crises usually happened then, when the lancinating pains in the lower extremities had been of a specially severe character. If the patient continues in the recumbent position, the attacks are somewhat milder than when he is restless. Raymond and Oulmout remark that one should not forget to look for stone in the bladder in such cases, which the blood seemed to indicate. In this case no stone could be found.

Nuclear-muscular Paralysis of the Eyes.

The symptom-complex of this disease, as described in No. 16, III, 82, of the *Deutsche Med. Zeitung*, and as mentioned already by v. Graefe and others, is as follows:—

When the general health is perfect and not in the least disturbed, a gradually progressing paralysis of at least all the muscles of the eyes (levator palpebrarum, superior included) develops itself. The bulbi are at the same time becoming more prominent. Some muscles may, however, be more paralyzed than others. The movement of the pupil and the power of accommodation are always intact. When the disease has reached its acme, the eyes are perfectly motionless. The malady is incurable.

Dr. Lichtheim, in Bern (*Corr. Bl. f. Schw. Aerzte* I, 2, '82), who seems to have given this subject special attention, believes the cause of this disease to be an isolated affection of the

motor oculi, of the abducens and the origin of the trochlearis, a lesion which affects uniformly a series of gray matters which are functionally connected with each other. He compares this complaint with bulbar paralysis (labio-glosso-pharyngeal paralysis), with which it has undoubtedly many points in common, only this eye disease never causes death. I. Hutchinson has observed seventeen such cases. Reports of post-mortem observations, with description of the brain, have not as yet been published.

Removal of Uterus for Malignant Disease.

In the *American Journal of Obstetrics*, Dr. T. A. Emmet reports the case of a woman, about fifty years of age, in whom, having made the diagnosis of cancerous growth just within the cervix, he decided to remove the uterus. He reached this conclusion because the general health of the woman was excellent, and he considered that he had encountered the disease in its early stage, which rendered such an operation justifiable. The womb was removed through the abdominal walls, and the bladder was unavoidably injured during the operation. To guard against peritonitis a coil of india-rubber tubing was placed on the abdomen, and according as there were rises of temperature ice water was made to flow through it. The patient died on the morning of the fifth day.

Diseases of the Eye Due to Masturbation and Sexual Excesses.

Prof. Herm. Cohn delivered a lecture on this subject in a meeting of the medical section of the Schles. Ges. f. Vaterl. Kultin. A report of this lecture is contained in the *Bresl. Aerztl. Zeitsch.*, III, 4, 82, and an extract of it in the *Deutsche Medicinal Zeitung*, III, 16, 82.

Cohn observed, in cases of masturbation, if practiced to excess, photopsia, conjunctivitis, blepharospasm and paresis of accommodation. Photopsia showed itself always as subjective light phenomena in young persons, the eyes of which represented a perfectly normal pupil, normal vision and tension, an intact sense of space, light and color, clear media, a perfectly healthy optic nerve and a normal retina. The patients had all kinds of phenomena. They saw spots, stars, light wheels, shining circles, or brilliant dots. In the majority these fata morgana ceased during darkness; in all, on closing the eyes. Of conjunctivitis Cohn saw six cases; blepharospasm due to masturbation generally attacked both eyes. If this contemptible habit may lead to amblyopia has not been demonstrated. Mooren already insists upon the relation between masturbation and paresis of accommodation. That glaucoma and morbis Basedowii happen in such cases has been mentioned by Förster and v. Graefe. In conclusion, Cohn recapitulates the view of neuropathologists concerning the dangers of this habit, and recommends as cure, convincing, by plain and public talking. The pupils, at a certain age, should specially be warned against it.

Erythrophleïn, a New Alkaloid.

Gallois and Hardy reported, some time ago, that they had been able to gain from the codex of Sassy (erythrophleum guineense) an alkaloid, erythrophleïn. Prof. E. Harnack, of Halle, communicates to the *Centralblatt f. d. Med. Wissensch.*, No. 9, 1882, the fact, that on further examination he had been surprised to find that this alkaloid unites the main effects of digitalis and picrotoxin; that it did not only possess the characteristic effect of the former on tne heart, but eauses also convulsions, due to irritation of the medulla.

This is of the more importance, as, so far, only substances free of nitrogen have been known to possess such an effect. Chemically, erythrophleïn is somewhat similar to atropia, especially as regards its products of decomposition.

Treatment of Fracture of the Femur in Children.

It is well known that Schede was the first who (1877) attempted the treatment of fracture of the femur in children of very young age (1 to 3 years) by vertical extension. Jarnbach (*B. Kl. W.*, 9, '81) condemned this procedure, saying that the permanent position on the back would cause affection of the lungs.

Dr. Herm. Kümmell, of Hamburg, reports now, in the *Berl. Kl. W.*, 4, '82, that he has treated 40 such cases, according to the method suggested by Schede, and he found that children, even badly nourished and under by no means favorable circumstances, had been able to withstand a permanent position on the back for as long as 111 days, without in the least suffering from it, as far as their lungs were concerned.

The *Deutsche Medic. Zeitung* specially mentions, in addition, that the result of this treatment in Kümmell's cases was excellent, as not a single case of dislocation in any direction, nor shortening of the fractured extremity, was observed, and recommends, very properly, the general adoption of Schede's method in all cases of fracture of the femur in very young children.

Acute Rheumatism and Salicylate of Sodium.

At the meeting of the Society of Physicians of Nieder-Œstreich (February, 1882), Dr. M. Heitler mentioned his experience in the treatment of acute articular rheumatism with salicylate of sodium. He found its action the most rapid and favorable in very acute and violent cases, while in such as run a more protracted course the remedy was far less reliable. The doses administered must not be too small, and have to be frequently given. He advised a daily dose of 160 grains to be given w thin five hours ; every hour 32 grains. When the symptoms decline the remedy should be employed the same way one day longer. The complication of endocarditis is in no way affected by this remedy. How the pulse is the guide, when to decrease the doses, we mentioned in a leading article on salicylic acid, some time ago.

A Marvel of Surgery.

Dr. Roswell Park, of Chicago, reports a marvelous case that he has recently seen in Prague. The great surgeon, Gussenbauer, more than a year ago removed the larynx and epiglottis of a patient suffering from cancer. Six weeks after ward he began to wear part of the artificial larynx, and after accustoming himself to this, he gradually learned how to introduce and use the reed which takes the place of the vocal cords. The patient is a riding teacher, talking a great deal, and does not suffer the slightest inconvenience or pain. His voice is monotonous, but his enunciation excellent, his speech perfectly intelligible, and he eats and drinks with perfect facility. Three intra-laryngeal operations had been previously made before Gussenbauer attempted his feat.

Tumor of the Cortical Substance of the Brain.

The *Pesther Med.-Chir. Presse*, No. 46, reports a very interesting case of a tumor of the cortical substance of the brain, presented by the Med. Corr., Prof. Wagner, in the University Clinic.

The tumor, of the size of a walnut, and apparently tubercular in character, was found in the left upper temporal lobule, and had caused softening extending to the posterior central convolution. The symptoms, which had been observed during life, and which may be ascribed to this tumor, were the following: Awkwardness and debility in the movements of the right hand, and two attacks of convulsions, beginning both times with spasm of the same hand. The second of these paroxysm, a very violent one, caused the death of the patient.

Correspondence.

Digitalis and Aconite.

Ed. Med. and Surg. Reporter:—

In your journal for June 3d, 1882, you give a short but interesting article on digitalis and aconite, which forcibly reminds me of my experience with those drugs.

The therapy of digitalis and aconite, as I got it thirty years ago, while a medical student, was of such a demoralizing nature, that I was for a long time deterred from the use of those valuable medicines ; and as there are others, perhaps, in the same condition, I will, for their benefit, give a brief statement of the results of my use of them.

Lectures and text books of the time of my student life seemed more for the purpose of frightening the young physician than teaching him their properties.

The "cumulative" action of digitalis and the powerfully depressing properties of aconite received much more attention in the lecture room than all else of their therapeutical properties.

The pharmacy of those drugs has improved as much or more than has our knowledge of their therapy,and their bad or uncertain effects are more attributable to the improper time of gathering, and the place and manner of their preparation for use, than to any real want of uniformity of action.

The *German tincture* and the "*specific*" tincture of the Eclectics are the only preparations of either that I use ; other preparations may be reliable, but finding those to always give responsive action, I use no other.

During the last ten years I have used digitalis a great deal, for the amount of general practice done, and perhaps in all the abnormal conditions of the heart in which that drug is indicated, without a single bad effect, except that all the cases did not recover : nor do I remember a case in which the physiological effect of the drug did not obtain.

In the intermittent or remittent pulse of cardiac disease, or in that of fevers, digitalis will give regularity to the circulation. And so uniformly does that result obtain that I look upon it as a heart tonic, as reliable as bark, and its salts are antiperiodics.

And so sure and steadfast are its tonic effects upon the circulation, that, were I to permit a typhoid case to enter the third week without digitalis I would feel that I was doing him great injustice.

I do not use it as, or believe it to be, a sedative at all like veratrum or antimony ; yet it will "slow" a quick pulse, but it is the quick pulse of debility.

If small doses, at short intervals, is the better way to use any medicine—and I think it true of most all—it is preëminently true of the two under consideration.

Of digitalis, I do not remember to have given more than two drops of the above preparations,

or more frequently, in that dose, than every two hours. its effects obtaining in twelve hours, sometimes much sooner.

In anasarca and ascites, conjoined with apocynum, it has in every instance given relief. In the bronchitis of the old, or very feeble of any age, with aconite, it is invaluable. Indeed, the whole therapy of digitalis may be summed up—and I dismiss it with this remark—it is indicated, and will give good results in all cases of feeble circulation.

An old gentleman of this place, with a complication of cardiac disease; effusion so great he could not lie down (pleural effusion as high as the nipple on both sides); so imminently perilous was his condition, we telegraphed to New York for an aspirator, but at once put him to taking digitalis and apocynum. In thirty-six hours improvement began, and before the aspirator came—some five days—he could lie down in comfort, and though the case terminated fatally several months after, he got those several months through by the supporting properties of digitalis. Other cases could be given, like his, but it is unnecessary.

Let me impress it upon the young physician, for whom this is especially written, yea let me emphasize it, give digitalis in small doses, and you need have no fears of "cumulation."

Dr. Fothergill, of England, has recently called attention to what he says is true—I have not seen it—that after your patient has been under the influence of the drug some time, a sort of paralysis of cardiac muscles takes place; that very pathological condition digitalis is wont to remove.

My friend, Dr. C. M. Sebastian, of Martin, Tennessee, stated, a few days ago, before the West Tennessee Medical Society, of which he is vice president, that recently he had a patient taking digitalis, in whom that condition obtained, which condition passed off on the discontinuance of the drug for a while, to have its good effects on its resumption, and so pronounced did the symptoms become of the paralyzing effects, that the patient learned himself when to discontinue it.

Is it not most likely that the paralysis that Dr. Fothergill speaks of is that condition that used to be, and is yet, called the "cumulative?"

In regard to the aconite, I start out with the broad statement that it is indicated in all inflammatory and febrile diseases in which there is a frequent small pulse; in the bronchitis of the aged, in the catarrhal affections of infants and children, be it of the stomach, bowels or air passages.

As veratrum is *the* sedative in many cases of full, hard pulse, sthenic disease, so is aconite *the* sedative in the frequent, small pulse, asthenic disease.

The sedative we want in all mucous inflammations, in common catarrh, a bad cold, eyes and nose running, sneezing, constant tickling in the trachea—add one minim specific tincture or fluid extract aconite to one ounce of water; give a teaspoonful every hour; it will surprise any one who has not used it thus. And as before said, and to sum up in a few words, aconite is indicated in all cases of inflammation in mucous tissues; in all fevers with small, quick pulse, if a sedative is desired, aconite is the one.

Trenton, Tenn. S. W. CALDWELL, M.D.

A Growing Evil.

ED. MED. AND SURG. REPORTER:—

We find in an American journal, apparently published for the advancement of our materia medica, but in reality serving the business interests of a wholesale drug firm, an editorial notice, headed "A Growing Evil," wherein physicians are blamed for not being "fully alive to the importance of *specifying continually* the name of the manufacturer whose remedies they prefer, when ordering from wholesale drug houses or in writing prescriptions."

Our opinion is exactly the opposite one. If there exists anything ridiculous, it is a prescription, as for instance, the following:—

℞. Elix. cinchon. ferrat. (John Smith & Co.) f℥ iv.
Ext. jaborand. fld. (L. Smith & Co.,) f℥ ss
Tinct. nucis vomic., (M. Tincture & Co.) f℥ ij
Syrup. limonis comp. q.s. ad (F. Syrup & Co.) f℥ vj. M.
SIG.—

A physician should know, in the locality in which his patients reside, every apothecary who is reliable, and only to such drug stores should he send his prescriptions to be put up. So-called proprietary medicines should, under no circumstances, be prescribed. The physician should write for such compound medicines only as are either recognized by the Pharmacopœia, or which are of his own composition, and the compounding of which is described in the prescription, while the apothecary is held responsible for the character of the drugs directed to be employed in the making up of the prescription.

Certainly, with sugar-coated pills, for instance, which cannot be made so well in a retail drug store as wholesale, or phosphorus pills, the minute division here necessary being better accomplished by machinery, and with similar preparations, the case is different. The same holds good with certain articles, as Squibb's, ether, etc., where the manufacturer has gained a deserved reputation for the purity and uniform strength of a certain medicine. But what we despise is the employment of any proprietary compounds in the composition of any prescription. Any elixir, mixture, syrup, pills, etc., put up and ready for sale by any drug house, should be discarded. The only use, especially pills of this kind have, is in hospitals and in country practice, where the physician must also dispense his medicine.

Our prescriptions should always be so written that they may be put up by any good apothecary in any civilized country of the whole world. If we write, for instance:—

℞. Olei morrhuæ, f℥ iv
Syrup calci lacto-phosphat., f℥ ij
Gm. acaciæ, ℥ vj
Misce ut fiat emulsio, ad f℥ vj.
SIG.—

any reliable apothecary in the United States, England, France, Germany, Italy or Russia would be able to put up the prescription, while an American traveling in Austria might find

difficulty in procuring his medicine on a prescription as follows :—

℞. Emulsion cod-liver oil and syrup lacto-phosphate of lime (cod-liver and co), f℥ vj.

The physician should be the one who, having judged all the facts bearing upon a case, directs the composition of the medicine indicated, and not the apothecary or wholesale druggist, who compounds a certain mixture, for which the doctor has to hunt up a case in which it might answer its purpose. The medicine must be prepared to suit the case, and not the case made to suit the medicine. **

"Self Abortions."

Ed. Med. and Surg. Reporter:—

I desire to relate the occurrence of several self induced abortions that have come under my notice :—

One case, I remember, was induced by large injections of water, alternating with hot and cold water, used every few hours. After the third day a two months' fœtus was expelled, followed by a profuse hemorrhage, which I was called to treat.

Another lady regularly aborted by introducing a common goose quill and leaving it within the uterus until expelled by uterine contractions. She had been advised to select the end of the third month for the operation, and she laughingly remarked "that she could flip their *eds hoff hevery* time." (She was English.)

I knew another lady who used, for a similar purpose, a common knitting needle, half an inch of the point of which was bent at an obtuse angle.

But the most remarkable case I ever knew came before me last winter. A tall, angular girl, about 20 years old, came into my office, and without hesitating, remarked that "she was in a fix, and was determined to get out or die." Said she had got something in her womb. I asked her what it was. She doggedly replied, "a button hook." I placed her in my chair and found about half an inch of the handle protruding between the labia. She had the point passed beyond the internal os, and in attempting to withdraw it the point imbedded itself firmly in the uterine tissue. There was some hemorrhage, and labor pains were pretty frequent. In her efforts to dislodge the hook she had dragged the uterus low in the pelvis. Seizing the handle with my left hand I introduced uterine forceps along the stem of the hook until they entered the neck of the womb. I then opened the blades so as to embrace the stem at the curve of the hook, and had little trouble in removing it. Labor progressed, and in a few hours was over with, the girl making a good recovery.

Janesville, Wis. H. S. Humphrey, M.D.

—The Japanese Government has lately drafted new regulations for marriages. According to these, no man in the empire will henceforth be permitted to marry before arriving at the age of twenty. Women, however, are to be privileged to marry at eighteen.

News and Miscellany.

British Medical Association.

The Fiftieth Annual Meeting of the British Medical Association was convened in the Guildhall, Worcester, on August 8th. The President, Dr. Strange, then proceeded to deliver his address, but before doing so, expressed his regret that so few foreigners had been able to attend the meeting. About fifty distinguished men in America and on the Continent had been invited, but only two or three had been able to accept. It was a matter of regret that such men as Charcot, Esmarch, Pasteur and others were not present among them.

PRESIDENT'S ADDRESS.

This occasion being the fiftieth on which the President of the British Medical Association had been called upon to make an address, the usual subjects discussed upon such occasions had been well nigh exhausted, in consequence of which the present incumbent felt much at a loss for a subject upon which to address his colleagues. Taking into consideration that this was the jubilee meeting of the Association, he had decided that the most appropriate topic for his address would be a review of the "Revival and Survival of Medicine," which (dividing the subject into two parts) he proceeded to discuss.

PART I.—THE REVIVAL OF MEDICINE.

The speaker said :—

Turn back with me now, in memory, to the decennium which fell between the years 1830 and 1840. The times were pregnant with mighty changes—political, social and scientific. To those whose memories are able to carry them still further back—viz., to the period immediately succeeding the close of the great Continental wars, the collapse which followed the exhaustion of the nations by those wars must appear a most noteworthy circumstance. This period lasted from 1815 to the financial crash of 1825. The political collapse appears to have been accompanied by a corresponding mental stagnation. Science, which loves to dwell with peace and gentle intercourse, had, indeed, been quietly working in their absence, unnoticed in the political turmoil, and had made frequent efforts to obtain a hearing, but no one listened. The pipers were, indeed, ready, but no one had the heart to dance.

When, at last, the calm of peace settled down upon the nations, the pent-up forces of intellect burst forth ; then was developed that new power of combination and association.

Combination, applied to the exercise of thought and to the diffusion of knowledge, resulted in the formation of those great societies of which the "Provincial Medical and Surgical Association" was neither the meanest nor the least valuable. The year preceding the birth of our Society—viz., 1831, had seen the "British Association for the Advancement of Science" launched into existence, our Sir Charles Hastings having been one of the original members. A few years before the Society of German Naturalists and Physicians had been instituted. And, in July, 1832, the foundation-stone of our own

Society was laid in this city, by its distinguished and ever-to be-respected founder, Charles Hastings, and his small, but devoted, band of coadjutors.

As there were great men in Greece before Agamemnon, so also there were great names in medicine before 1832. There were, however, in those days, giants indeed, the like of which, at one period of time, the world has rarely, if ever, seen. Recall to your minds the names of Wilson Philip, who once lived here in Worcester; of Lawrence, of Abernethy, and of Cooper, all of whom, however, were already passing away; and then of Copland, of Latham, of Marshall Hall, of Brodie, and of Watson, in England; of Barclay, and Gregory, the Monroes, and the Thomsons, of Knox, Alison, Bell, and Christison, in Scotland; of Graves, and Stokes, and Colles, and many others, in Ireland. Nor was the Continent in any way behind us. I, myself, had the pleasure and advantage of hearing Louis expound Lænnec, and of literally sitting at the feet of Andral, Chomel, Magendie, Roux, and Milne-Edwards; while Rokitansky, Scoda, Liebig, were raising the German school of medical philosophy from out of its backward, or, at least, little known, condition, toward the pitch of eminence to which it has since attained. And not only was it in medicine proper that this great advance was being made. Biological science generally was reaping, in this generation, the benefits conferred upon it by the one which preceded it. Bichat and Barclay, Prochaska and Wilson Philip, were followed by Magendie and Fletcher, by Milne-Edwards and Marshall Hall, by Charles Bell, Brodie, and Hope, and by a host of others second only in fame to those I have named.

These men all offered for our admiration and imitation two prominent characteristics: patient research and observation of facts, and thorough conscientiousness in the use of them; and unswerving courage and truthfulness in announcing these facts to the world. The days of unquestioned dogma were passing away. No deductions were drawn from a few meagre facts, warped and manipulated to fit them to a preconceived theory; but the true Baconian system was honestly adopted, and no conclusions come to but such as as were justified by the data at command. Compare the diction of Lawrence, of Bell, of Latham, of Watson, of Gregory, Alison, and Christison, of Graves and of Stokes, with that of their contemporaries in any other field of literature, and you will not have to blush for the great physicians and surgeons of that day. Of our own Watson, you know it has been said that he made the "Practice of Physic" to read like a novel; and, in this respect, I think I may call him the Macaulay of medical literature; while the terse and transparent style of Latham and of Bell bears a close resemblance to that of Connop Thirlwall, who, it is said, made but an indifferent bishop, but would have made a first rate Lord Chancellor, or a great physician. I do not like to say anything ill-natured of the style and diction of some of our modern medical authors; but, all the same, I think their time would be not altogether wasted, if, before putting pen to paper, they were carefully to peruse and re-peruse, the works of the older writers to whom I have just referred.

No wonder, then, that in such progressive times, to a mind like that of Hastings, the cold stagnation of a small provincial town was unbearable. He read papers and started journals and societies on a small scale, but it was not until 1832 that he received sufficient encouragement to venture upon that step which he proposed should result in placing the provincial practitioner in almost as good a position as his metropolitan brother. The speaker then gave a description of the provincial physician of that day, which was much like our country physician. The aim of our founder was, that knowledge should be freely and generously communicated by the free and generous intercourse between hitherto separated and scattered individuals. That this aim has fructified so as to justify its conception is, I venture to think, proved by what we see here to-night; by the vast numbers who now call the British Medical Association their professional parent.

In closing the first portion of his address, the speaker said, I fear I have wearied you with these references to an almost forgotten past. But, if it is good for us to look to-day, before and after, upon what we *were* and upon what we *are*, in the hope that we may find a true beacon-light to guide us in the course on which we are now entering, viz., our onward journey in company with the second half of the century of the existence of the British Medical Association, I think the reference will not have been altogether out of place; for, if our fathers did greatly with the limited means at their command, we, with our far vaster opportunities, shall be expected, at least, to equal their deeds. If they laid the foundation of all that is valuable in our modern medical literature; of all that is exact and trustworthy in our scientific precepts: of all that is honest, free, and catholic, in our investigation of truth; of all that is liberal, sympathetic, humane, in our intercourse with each other, and with the world; I think it is due to them that this jubilee—this commemoration of the past and inauguration of the future—should not be allowed to pass away without justice being done to the memory of those whose labors have so greatly contributed to make such a meeting as the present possible.

In this imperfect and necessarily hasty attempt to trace the history of the medical mind during the past half century, I have made no mention of medical politics. Nor do I intend to do so now. A President's address, it is said, as it admits of no discussion, so it should contain no disputable matter. But I may briefly remind you that the great corporations which guard the entrance into our profession, and fix the initial requirements from each candidate, were at length roused from their long apathy, and their exclusiveness was finally broken down by the same active minds of whom I have spoken—those minds who determined that everything connected with medicine should be free. The College of Physicians, before so exclusive, somewhere about 1860 threw open its doors and its honors to all qualified applicants, come from what college or university they might. The College of Surgeons had somewhat earlier given an impetus to enlarged studies by the establishment of its present fellowship

examination; and the sister establishments in Scotland and Ireland soon had to follow suit.

PART II.—THE SURVIVAL OF MEDICINE.

It has been often enough said, but never more to the point than by Dr. Acland, in his address to this Association, at Oxford, in 1868, that "there are certain landing places in a man's life where it is desirable that he should pause and think." Let us pause here, in this landing-place of our existence, this point between the fifty past and the fifty coming years, and look about us, and ask ourselves what manner of a profession ours *now* is? what is the condition and tendency of its mind? what are its aims? and what are the means by which it seeks to accomplish these aims?

Fortunately for our profession, we enjoy absolute liberty in our practice. We have no senate to revise and over-rule the decision of the commonalty of medicine; no courts of appeal, like our friends, the lawyers. We enjoy freedom to think; freedom to speak; freedom to write; freedom to teach!

The great corporations, so long as we do not get convicted of felony, leave us pretty much to our own devices. Neither do they set up any standard of correctness, either of theory or practice. There is no theory which we may not promulgate; no practice, short of manslaughter, which we may not pursue. An unfettered press and open criticism are the courts before which all claims to new discovery, to improved practice, to advance in knowledge, must be brought. All must stand or fall by their own merits. Still, great names have their weight. The words of a Jenner, or a Paget, compared with those of little known authors, are as the discharge of an eighty ton compared with that of a pocket-pistol.

Over the church and over the law, for obvious reasons, it may be desirable that the State should hold a check; but over the investigations of science, and over the application to practice of that science, we will have no master other than the moral conscience of our profession itself.

The advantages of this liberty are obvious. It must be the verdict of the profession itself which shall say, "Well done, thou good and faithful worker, be thou rewarded for thy faithfulness to truth, to nature, to humanity, by the acclamations from the thankful and reverent hearts of thy brethren." This is the true gold. This is the patent of nobility conferred on real merit.

Liberty unrestrained, may, however, degenerate into license. It is this spirit carried to excess which forms one of the nuisances of modern medical literature, when many a fresh investigator will treat his subject as if no one had ever done anything in it before; when many a young observer must narrate what he sees as if it had never been seen before; parading as new what may, perhaps, be found in Hippocrates or Galen; or, at the least, repeating in book and lecture what has been better said a hundred times before. Our current literature swarms with instances of this nuisance, for a nuisance, and a real weariness of the flesh it is to all readers who know the literature of their profession.

Self-assertion! Self laudation! Self-sufficiency! and then the one step further ——! Gentlemen, the quackery, the charlatanry, that exists outside the profession will never hurt us. It is the quackery, the charlatanry, the false pretence, the dishonest self-seeking to be found within the profession, which, if unchecked, will bring disgrace upon us.

A great characteristic of modern medicine is philanthropy; we ignore our own personal advantage whenever it is placed in opposition to the good of our patients. Is not sanitation and the legislation which promotes it the work of our profession, and do we not almost invariably, when entering a house, inquire into its sanitary condition, and when discharging a patient, cured, give him such advice as is calculated to prevent him from again falling into our hands? The public are beginning to feel that ours is not a mere trade, so much attendance for so much money. They are even inclined, some of them, to pat us on the back and call us noble fellows. But be on your guard! Much of this praise is false pretence, and given with the covert intention of trespassing upon your time and labor in an illegitimate manner. I think I have established our claim to two great Christian virtues, viz., true liberty, and charity, or love.

What then remains to complete the Christian triad? Is it not Truth; Truth to nature; truth to ourselves; truth to our brethren and to the world? Are our studies and researches carried on in the sincere desire to attain the truth, and the truth alone? Is our teaching animated by the same principle, and by nothing else? Are our practice and our intercourse with the world regulated by the all-sufficient motto, "Let truth prevail, though the heavens fall?" If we all could answer these questions by a bold and honest "Yes," I should have no fear but that our profession will, in time, arrive at that high pinnacle of usefulness and exalted public appreciation which two great men have foretold for it. It was no less a man than Descartes who foretold that a great future was in store for us. All science, and almost all knowledge, was to be drawn upon to furnish the physician's mind, and then, he said, "all things would be open to him." No less a man than Lord Beaconsfield uttered nearly the same idea. If, therefore, these far-seeing men presaged such things for us if the light of truth were consistently followed, what a failure must it be if truth be lost sight of! If this great light that is in us be turned to darkness, how great indeed must that darkness be!

The spirit of our age tends toward a general *laissez faire;* allowing every one to follow the direction of his own mental bias, or even whim, whether the project be theory or practice. But there must be a right and a wrong road in all intellectual and moral action. Truth being many sided cannot be confined within fanciful bounds. The scientific mind must be perfectly free and open, not enslaved by reverence for a name or by predetermined dogmas.

Nor can there be any real fellowship between honest truth and consciously pursued error; for, independently of contradiction of belief, the lines they severally work upon diverge until they no longer touch at any point. To agree to differ, therefore, is not enough; there must be utter repudiation the one of the other.

And then, in regard to practice, are not the same faults to be discerned? Are there not in our ranks those who conduct their practice under what I may call an organized hypocrisy; men who assure one class of their patients or dupes of the hope of cure when cure is impossible, and given up by all honest men; who assure another class of the existence of serious maladies which no one else can see, and treat them for months or years for ailments which do not exist, or, existing, are of no importance; while guinea after guinea is extracted without mercy, or regard for the means of the patient, or to the real services rendered? By these vile arts the character of a noble profession is dragged in the dust, and fraud, detected in the guise of science, hangs her disgraced head.

Some of these faults owe their existence to the ignorance and caprices of our patients. It would be laughable, were it not lamentable, when the issues of life and death are concerned, to hear the reasons which often guide our patients in seeking what they call "further advice."

One wretched form which this assumption of independence of judgment takes is the resort to advertising quacks, not only those without, but also those within the profession. And then, as regards consultants, do we not recognize a solemn farce when Mr. A. or Mrs. B. returns from consulting, say, some metropolitan celebrity, and tells us that Dr. C. has laid down all the rules for his or her future life, and indicated this or that health-resort as essential to recovery; and all in ten minutes' time and for a fee of one guinea? The issues of life and death, in the case of a stranger never seen before, solved in a ten or fifteen minutes' interview, and all for one guinea? Why, a lawyer would take six weeks to do the same amount of work, and charge a bill of fifty pounds. Such practices on the part of the public must needs tend to relax the morals, and to sap the strict integrity of professional men.

Commenting on the force of example, the speaker said, in these days of liberty of action men are jealous of the control of individual authority. As I have already said, we are a re public; we have no king, either constitutional or despotic. The heads of our colleges are that and nothing else. But, although men will not yield to the dictation of individuals, however eminent or highly placed, will they not submit to the control of their fellows, jointly? Would not the great principle of association be found equal to the *moral* guidance of individual members, as it is to securing their political and professional rights? We know how great is the power of example, which induced the scoffer, who entered the church to sneer, to remain to pray. In the way of moral suasion, the power of numbers is, I believe, even greater than in that of political bias. So, to the voice of the profession, adequately expressed, it is fitting, and, I think, feasible, that every member should ultimately bow.

May I venture to conclude this discourse in words far more eloquent than any I have used, or can use. Words which I wish would sink, this night, deep into the hearts of us all; words of the late wise and good Bishop, to whom I have already referred. "When such a spirit (as that I have endeavored to depict) shall become the prevailing spirit among us, the sick-room will become holy ground—a temple ever ringing with the exhortation *Sursum Corda!* Upward, hearts! Upward above all paltry, sordid, groveling aims and desires. Upward to the level with the dignity of our calling; the privileges and duties of our station; the importance and arduousness of our work. Upward to a fellowship with the wise and good of all nations. Upward to the very Father of Lights; the Fountain of all Goodness! Lift up *your* hearts; and then, from the very depths of thousands of yearning, anxious souls, there will arise the clear response: Yea! we lift them up unto the Lord!"

At the conclusion of this address, Mr. Fowke, the General Secretary, read the annual report of the Council, which shows the Society to be in a most flourishing condition. The receipts for the past year were $82,625, an increase over 1880 of $4480; 715 new members were elected, and there were 76 deaths Concerning the mooted question of homœopathy the Council report that—

"As far as is possible, they have rigidly closed the door of entrance, and have made it impossible for a professing homœopath to enter the Association through election by the Committee of Council; and they have called upon the Branches to aid them, by demanding that every name proposed for election shall be inserted in the circular summoning the meeting at which election is sought.

"They conceive that, by these means, such effectual supervision will be exercised by the Branch Councils that no homœopath will be able to gain admission, either through the Committee of Council or through the Branches; and that thus both doors of entrance are effectually closed.

"Against perversion to homœopathy after admission, they are, at present, powerless, except by the expulsion of the offender; and this, under present circumstances, they consider unadvisable; first, because they hold that such a course would be beneath the dignity of the members of a great liberal profession; and, secondly, because it would confer an amount of notoriety which is very undesirable upon those who were expelled.

"At the same time, the Committee of Council courts a full expression of opinion on the part of the whole Association, as to whether it will tolerate homœopathy in its ranks or not; and, if it should determine that the profession or practice of homœopathy shall—*ipso facto*—disqualify from membership, then they conceive that the course will be clear, since the unwitting election of a homœopath would thereby be rendered null, and perversion after election would imply the voluntary cessation of membership."

After considerable discussion upon subjects only of local interest, the report was adopted and the Society adjourned for the day.

Second Day, August 9th.

After the transaction of routine business Dr. Wade delivered the Address in Medicine. Like the President's, Dr. Wade's address was retrospective in character. He recalled to mind some of the actual facts of medicine as it existed when

this Association was formed, and some others which have occurred since. The sum total of knowledge increases fast, but the capability of individual intellect slowly, if at all. It is not a question of who makes mistakes and who does not, but of who makes the most and who the fewest. Looking at the records of the past, we find that current errors were shared by men who were in the front rank of the profession, and who, did they flourish in these days, would be in the front rank now. No one of the present generation reading for the first time the clinical memorabilia of 1832, can fail to be struck by one all-pervading method of treatment, viz: blood letting. The difficulty is to name diseases in which it was not used, not those in which it was. Its prevalence may be brought very vividly before us by a quotation from a contemporary author. He says: "Blood letting is not only the most powerful and important, but the most generally used, of all our remedies. Scarcely a case of acute, or indeed, of chronic disease, occurs, in which it does not become necessary to consider the propriety of having recourse to the lancet, or to estimate the effects of blood letting already instituted." But, to get a full impression of this frequency, you must read, one after another, the records of cases in which—medical, surgical, traumatical, and obstetrical—bleeding from the arm was practiced. Indeed, this does not exhaust the category. The chief resource of preventive medicine was to let blood from the arm every spring and fall.

Such was the practice of that day, and such, in large measure, the therapeutical science; for, be it observed, these things were done, not only by obscure apothecaries, but under the direction and auspices of those who constituted the highest court of scientific appeal.

Not many years before 1832, a weekly medical journal, which still maintains its high character, was instituted, under the then appropriate name of "*The Lancet.*" In a few years after this date the title of this periodical had well nigh become an anachronism.

Within those few years a revolution of opinion had taken place, the like of which the history of medicine wots not of. For, be it remembered, this was not the case of a transient phantasy—of a gourd which, having sprung up in a night, might well wither in a day—but the well established practice of centuries, which had withstood, not only the ravages of time, but repeated volleys from the batteries of wit and satire.

The disuse into which blood letting has fallen is due principally to the fact that our predecessors misused it.

In 1820 a provincial practitioner, a physician at Nottingham, Marshall Hall, opened the first parallel of the siege which, in my opinion, eventuated in the razing of this stronghold.

In 1836, Marshall Hall's last work on blood letting was published. But a very few years elapsed before it had ceased to be practiced. It is curious that the intention of his publication was to regulate, not to abolish venesection. He taught its value, and recommended its employment, but with limitations not hitherto laid down. Men came to look at bleeding from an exactly opposite point of view to that which they had previously occupied; can we then wonder that in a few short years the practice had ceased to exist. Sir Thomas Watson, however, ascribed the decline of venesection to another cause, namely, a change of type in disease; writing in 1867, he says: "What has not been shown is that the human constitution is incapable, from influences to us unknown, of undergoing alterations, in respect to the manner in which it is affected by inflammation and by the reputed remedies of inflammation. For my own part I am firmly persuaded, by my own observation and by the records of medicine, that there are waves of time through which the sthenic and asthenic characters of disease prevail in succession; and that we are at present living amid one of its adynamic phases." To illustrate the fact that many other therapeutic measures (besides venesection) have fallen into disuse on account of abuse, many articles were mentioned and the speaker said:—

It is not so many years ago that there flourished a great clinical teacher, famous alike in the wards of an important metropolitan hospital and by the bedsides of the wealthy. Is it a truism that, to be sound, medicine must be based on physiology? He was an assiduous cultivator and eminent teacher of this science. In the zenith of his fame he sought, as you all know, to establish the plan of treating acute diseases by alcohol in almost unlimited quantity. Is it surprising that his views—earnestly enforced by word of mouth and in fascinating essays, propagated by an enthusiastic and numerous band of disciples, and not without an important substratum of truth—is it surprising, I say, that his precepts became popular, and that his example was for a time largely followed? What is our position now with regard to alcohol and its administration as a drug in acute diseases? Exactly what it was before this mischievous delusion arose. There is no acute disease in which alcohol is necessarily required. On the other hand, there is no acute disease in which special circumstances may not arise which necessitate its use in small, or in large, and even in very large doses.

The medical mind never has ceased, and probably never will, to hanker after specifics.

We see the chemist with his glass vessel full of carbonic acid in one hand, and in the other a lighted taper. He dips the wick in the carbonic acid, and the flame is extinguished. The result is immediate, decisive and unfailing. Can we be reproached for wishing that we might in like manner take a pneumonia in one hand and a vessel full of alcohol in the other, and by a similar immersion procure a similarly decisive and unfailing result. We might, perhaps with equanimity, submit to its being less immediate. Depend upon it, that to those who harbor such a wish, and indulge in contemplating the possibility of its fulfillment, the danger is great of erroneously believing that they have achieved the result. The danger is still greater that they will come to look at many drugs in the light of quasi-specifics, and so relax watchfulness over their effects.

It is true, probably, that no one of us believes in the existence of an absolute specific, which can never fail; but, on the other hand, we must re-

member that the conception of a specific and the conception of failure are reciprocally exclusive. A vivid mental picture of the one necessarily implies a very shadowy perception of the other. One reason why this yearning for specifics is so likely to mislead us is that it almost inevitably involves a conception of disease as a unity, instead of a complexity, of processes.

A "case" of pneumonia is compounded of two parts. The first of these consists of those local changes which are summed up in the phrase "the inflammatory process." It is true, though we do not need to dwell upon it, that even this phrase suggests multiplicity rather than unity. But there are also, as in all cases of inflammation, not only the local focus, but the influences radiating therefrom, and affecting all the organs and constituents of the body. In no disease is this duality better exemplified than in pneumonia, and hence this disease has been so often, in times past, a battlefield for therapeutists. In no disease does this duality require to be more explicitly recognized, because in none is death more often distinctly due to these secondary disturbances, and the danger so little in proportion to the cubical area of the original disease. It is true in all acute diseases, though especially so in this one, that the difference between life and death turns oftentimes on the possibility of rectifying some quite secondary functional disorder, as of the kidneys, the liver, the heart, or (in a single pneumonia) of the other lung. If we cannot unload the camel, we may nevertheless succeed in a timely removal of the last straw. It is true of all acute diseases, that a proportion will, under the most unfavorable circumstances, recover, that another proportion, will, under the most favorable circumstances and the most sagacious treatment, die. But there is a residue in which the issue is in our hands, to make or mar. Which we do, depends, in the main, on the soundness or unsoundness of the abstract principles which underlie our actions. And here let me beseech you in your mind to keep every case in this third category till all danger is gone, or till, on the other hand, death, not in your judgment is impending, but has actually commenced. The desire for a specific is an instinct, and will, therefore, be ever lurking in our minds; and it is because I believe it to be a dangerous conception when translated into practice, that I have dwelt on this question with sincere, if tedious, earnestness.

The connection between debility and disease, as old as true and as true as old, has been advanced by degrees till, in many minds, they appear to have become convertible terms; not, perhaps, avowedly, may be not even consciously, but so effectively as to dominate all other therapeutical conceptions. This position is not tenable. The body enfeebled by insufficient food may yet have its component parts and organs sound and their functions maintaining their due balance and complementary proportion. Practically, taking the case of acute disease, we do not find that the difference in the previous vital status necessarily indicates a decisive difference in the treatment. Take, for instance, two cases of typhus, the one occurring in a person previously in good health, the other in a subject previously reduced by want; it does not follow that in the latter alcohol will be requisite in larger doses than in the former. As a matter of fact we know that the very reverse may happen. It seems to me difficult to get away from the theoretical proposition that the best way to relieve the debility arising from disease is to remove or mitigate the disease. The progress of medical science has, for some time, been most marked in the elucidation of the nature and results of organic disease. The hopelessly irremediable character of the changes here found has certainly tended to enforce the idea of "nourishing, supporting and building up." From this point, the same idea has spread to an earlier stage in such cases, the stage of incipient disease, or to an even earlier stage, that of threatening or impending organic changes—a pre-organic stage. Has it not happened that this truly important consideration has been allowed to overshadow other important considerations. If it be important that we should get a complete mental grasp of the whole of a case, it is mainly so that we may be the better able to disintegrate it into its constituent elements; that, having so resolved it, we may the better see what we can and what we cannot cope with. How it might have altered the past, had the custom been universal for each one to ask himself, before deciding on a plan of treatment, these questions: What do I propose to aim at? Why do I do so? How best may I effect my object? Might not such a method also alter the future. Dispassionate survey of present medical practice forces me to the conclusion that, on a very large scale, and in both chronic disorder and organic disease, the physiological basis of treatment is too often unduly subordinate to the restorative basis of treatment. Analyze, each one for yourself and in your own way, the conceptions and the practices of those who have gone before. Above all, analyze your own conceptions and practices. Principles, to be effective, must be bone of our bone, and flesh of our flesh, not foreign bodies, howsoever much embedded or encapsulated. Is the history of medicine from this day to be reversed. Are we in future to be confident that no false prophets will arise; that we shall be safe in believing that all we are told is true. If not, how are we to refuse all the evil and choose all the good. The authority of the teacher, as we have seen, is no infallible test, for the evil may come from an oracle well calculated to command our assent. We must, to a large extent, depend each one upon himself, his own observation and his own private judgment, employing the best means and devices of science to ensure accuracy of observation, and exercising our judgment with caution and modesty. To the few only is it given to extend the landmarks of science or to reclaim the waste lands of ignorance. But to each one is given the power to cultivate and utilize those which have been reclaimed. To each one it is given to make the practice of medicine more rational, more common sense, and, therefore, more truly scientific; to render more rare in the future such dark blots as we have regretfully recognized in the past.

Dr. Cuming (Belfast) said he had great satisfaction in moving the best thanks of the Associa-

tion to Dr. Wade for his very able, thoughtful, and carefully reasoned address. They could have no better introduction to the work of the Sections than listening to the observations of one so competent to make them—observations which embraced a comprehensive view of their present position, and which analyzed so clearly, and appreciated so fully, some of the most important movements and currents of opinion that had been prevalent in medicine for some years past. Every one who, like himself, had been familiar for many years with Dr. Wade's important contributions to medical science, would have expected him to deal with the subject in a careful and interesting way, and to present the results of the ripe experience of a thoughtful physician and an acute observer.

An invitation was read and accepted, to hold the next session of the Association in Liverpool; after which the Association adjourned for the day.

Third Day, August 10th.

After the usual business, the address in Surgery was delivered by Mr. W. Stokes, of Dublin. The speaker commenced by expressing his appreciation of the honor that had been conferred upon Irish surgery in asking him to deliver this address. After referring to the great results achieved by the Association, the speaker said: But, great as have been the results of these efforts of the Association, much yet remains to be achieved. I should like to see loyal and hearty co-operation with the universities, the medical and surgical corporations of the United Kingdom, and the General Medical Council, to raise the standard of Arts education for all joining our profession, by establishing conjointly an examination in Arts which every one, except those with university degrees, should pass previous to commencing the study of medicine. I should, also, like to see a consolidation of the great medical and surgical teaching power that exists in our metropolitan centres, but which, owing to the multiplicity of small schools in them, is, to a great extent, lost to the profession and to the public. Instead of urging the establishment of additional schools, it would be far better to endeavor to bring about such an amalgamation as I have indicated, and coöperate with those who wisely think that among the chief desiderata in our profession is a large amount of training in a university, where the first phases in the life of a medical student can best be spent, viz., first, the preliminary general, and second, the preliminary scientific education. I am strengthened in this conviction by the fact that during the Visitation of Examinations recently conducted for the General Medical Council, in which I had the honor of being associated, the Visitors frequently observed candidates for the diplomas of our corporations whose general and scientific culture was far below what any one joining our profession ought to have.

It has hitherto been customary for my predecessors, at the annual meetings of the Association, either to give a *résumé* of the most recent advances in surgery, and discuss some particular theory or mode of practice on which surgical opinion is more or less unsettled, or dwell on those topics that have proved of special interest to himself. On the present occasion, one which should be marked *meliore lapillo*, to give a detailed retrospect of surgical advancement during the past half century would be a task not alone difficult, but, in truth, impossible in the time at my disposal. I purpose, therefore, to dwell on some few topics of great general interest, involving questions still unsettled, and which more particularly engaged my attention.

What have been these advances? I may mention a few that stand out boldly. The abandonment of an indiscriminate blood letting in almost every form of acute surgical disease, of a reckless use of mercury in the treatment of syphilis, and of setons and moxæ in hopelessly irremediable articular and other diseases; the introduction of the pressure treatment of aneurism by Bellingham, Todd and Hutton; of drainage in the treatment of wounds and abscesses by Chassaignac; of metallic sutures and the perfection of the operations of vesico-vaginal fistula by Marion Sims; of lithotrity by Civiale, Thompson and Bigelow, and of stricture by Syme, Wheelhouse, Maisonneuve, Perréve, and Holt; the *rénaissance* of joint resection by Crampton, Syme, and Ferguson; the introduction and establishment on a firm basis, of ovariotomy, by McDowell, Clay, Spencer Wells and Keith; of bloodless surgery by Esmarch; of skin grafting and sponge grafting, by Reverdin and Hamilton; and of osteotomy in genu valgum, by Ogston; improvements in methods of amputation, by Bell, Teale, Carden, Syme and many others: also the operations of gastrostomy, excision of the pylorus, of the spleen, kidney, supra-pubic excision of the uterus, laparotomy, and cholecystotomy in connection with abdominal surgery. I would also allude to the recently published able essays by Sir William MacCormac and Dr. Marion Sims, the latter paper dealing mainly with antiseptics and drainage in gunshot wounds—these being, in Sir James Paget's opinion, "the most important, perhaps, of all the provisions to be made in healing wounds." Again, we have torsion in the treatment of hemorrhage—a method to which such an impulse has been given by Mr. Bryant; and the treatment of aneurism by arterial ligation, without injury to the deeper structures of the vessels, by the methods of Porter and Barwell. In two cases I adopted Porter's method, using a wire, deligating the femoral artery in one, and in the other the abdominal aorta, Barwell's ligature—made from the aorta of an ox—a method recently tested in the Richmond Hospital by my colleague, Dr. Thomson, who deligated the arteria innominata for subclavian aneurism. Again, we have, in the treatment of fractures, immovable splints, and improved methods of extension by weights, or more perfectly by screw action; of manipulation in the treatment of luxation; and in spinal disease, the use of the plaster jacket of Sayre. The speaker then discussed the question of anæsthetics. In the majority of cases he would unhesitatingly prefer ether to chloroform, and strongly recommends the rule formulated by Mr. Jonathan Hutchinson, in reference to the desirability of using chloroform in cases below six and above sixty years of age. To Simpson is undoubtedly due the credit of discovering, in 1848, the anæsthetic properties of chloroform;

still, we must cordially, willingly and gratefully, endorse the opinion of Professor Gross, that "if America had contributed nothing more to the stock of human happiness than anæsthetics, the world would owe her an everlasting debt of gratitude," for it was in Massachusetts, in 1846, that Morton first demonstrated the possibility of inducing anæsthesia by the inhalation of ether. Antiseptic practice should rank, in my opinion, as the greatest of the surgical advances which the past half century has witnessed. In reference to Mr. Lister's statement as to the value of carbolic spray, at the International Medical Congress, last year, about which there has been so much unfortunate misconstruction, I would certainly say that he did not surrender his position in any way. He merely said that he looked forward to obtaining a more perfect and convenient mode of asepticism than that afforded by carbolic spray. The essentially weak point in the persistent and obstinate opposition to Listerism is the almost universal admission of the truth of the germ theory of putrefaction. If the fantastic theory of heterogenesis had not long since been swept into the deserved limbo of other exploded doctrines, there would be some scientific standpoint for those opposed to Lister's theory and practice. But not having this, and admitting the truth of the germ-theory of putrefaction, they surrender their position.

Those who advocate and practice what they are pleased to term a "modified" antiseptic system, attempt, in fact, in a roundabout, clumsy, inefficient way, to do precisely what those who practice Listerism achieve by means which are the outcome of accurate scientific research.

The aim in both cases is to neutralize or destroy the agencies which predispose to and produce the *materies septica*—in the one instance by numerous uncertain and often inefficient methods; and in the other, by the unerring artillery of chemical agency.

Among many depreciatory remarks that have been made in reference to Listerism, is one based on its alleged want of originality. It has been stated that both antiseptic principles and practice were understood, recognized, and appreciated by many of Mr. Lister's predecessors and contemporaries. Foremost among the latter, M. Maisonneuve has been mentioned. Having attended the *clinique* of that eminent surgeon for two sessions, in 1864-5, I am in a position to mention the nature of the wound-dressings then employed by him. With a large syringe, a quantity of a weak solution of "*acide phenique*" was applied to the wound; then a piece of linen or cloth, perforated with numerous openings and covered with a yellow-colored grease, was placed on the wound, secured by a dry compress and bandage. Such were the antiseptic dressings of which Lister's, it is alleged, are only a somewhat complicated, expensive, and, in many cases, dangerous reproduction. One of the best tests, if not the best, for the value of antiseptic practice is resection of the knee-joint, as there are so many circumstances that militate against immediate union being obtained after it. In the first place, the cases requiring so formidable an operation are, as a rule, in a condition of great physical exhaustion consequent on long confinement, and probably protracted suffering of mind and body. The wound is of necessity a large one; the operation occupies a considerable time; two large freshly cut bone surfaces are made, between which union is to take place; and, lastly, there is the great difficulty of keeping, no matter what appliance be adopted, the limb absolutely at rest during the process of union. Before the adoption of Listerism the surgeon anticipated that four, six, or eight months, or longer, would elapse before union took place, and it was always a subject discussed at consultations on these cases previously to operation, whether the patient would have strength to endure so protracted a suppuration. As an illustration of how changed matters are now, in a series of fourteen of my cases of excision of the knee-joint, the wounds in nine of them united without a trace of pus production; and in the last of them only two dressings were required subsequent to the one applied at the time of the operation, and in seven weeks after the patient was up and going about. Another antiseptic triumph was the case of a boy with extensive necrosis of the fibula, sinuses, and suppuration existing at the time of the operation. I excised, subperiosteally, the diaphysis of the fibula, and the case pursued a perfectly aseptic course, the evidence of new bone formation being also incontrovertible.

In giving the details of these antiseptic triumphs I may be considered dogmatic and egotistical. If so, I regret it, for nothing could be further from my desire; still less would I seem captious or actuated by any partisan spirit. I have mentioned them solely through a desire of having the truth recognized and established, and because personal experience is the soundest basis of honest conviction.

The speaker closed his brilliant defense of Listerism in these words: "In the interests and for the credit of British surgery, it is time so unrighteous a warfare should cease. It is time that the irritating dust of an unreasoning prejudice should be swept away. It is time that one of the greatest discoveries and boons to surgery this century has produced should be universally recognized as such. It is time that its discoverer and exponent should be acknowledged as one of whom it may well be said—

"With Genius, Nature joins in everlasting covenant still;
The promises of one, the other fails not to fulfill."

Discussing the question of bone production from periosteum, the speaker said, "As to its value when the membrane is comparatively healthy and the patient young, there can be no question. The activity of bone production and other signally gratifying results of the practice must be acknowledged when performed under these circumstances. These results, however, are not so striking when the patient is an adult."

As regards bone transplantation I cannot speak from any personal experience; but, in connection with this all-important subject, I must allude to the great stride made in this direction by Dr. M'Ewen, of Glasgow. The case of interhuman osseous transplantation, in which over two-thirds of a humerus was restored, and an account of which was communicated to the Royal Society last year, is one which must stand out in

bold relief in the history of this new departure in operative surgery—one which is, with many others, an outcome, indirectly, perhaps, but not the less, a result of antiseptic surgery.

In another group of operations—namely, in amputations—the preservation of periosteum is, according to Von Langenbeck, Trélat, and others, attended with advantage. The formation of a periosteal curtain to cover the cut surface of the bone and its medullary canal is believed to act as a shield or barrier against septic agencies, and diminish the chance of the occurrence of some of the secondary calamities, notably osteomyelitis, following amputations. The method I have in some instances adopted, and with success, is, making a somewhat quadrilateral-shaped flap at the membrane and letting it fall over the cut surface of the bone. Another method, that of M. Trélat, is to detach the membrane all round the bone for fully an inch below the point where the bone had to be divided, making, in fact, a sleeve-shaped flap. This plan must, however, materially protract the operation.

This leads me to consider some other comparatively recent improvements in the operation of amputation, and to bear my testimony to the great advantages to be derived from the adoption of the principle of long anterior flaps, the chief credit for establishing which belongs to the late Mr. Teale, of Leeds; and it is a source of pleasure to me that the advantages from his method of amputation were so soon, and continued to be so fully, recognized and appreciated in Dublin. In reference more particularly to thigh amputation, I cannot refrain from noticing the procedure in which the principle of the long anterior flap is embodied—namely, the "single flap" or "single-skin flap" operation of the late Mr. Carden, of this city.

Gritti's operation, undoubtedly, owes its parentage to that of Carden; but, although the retaining of the patella and consequent preservation of the normal attachments of the extensors of the leg is a plan as good as it was original with Gritti, still the details of this method prevented the realization of those advantages which, in principle, it embodied. Hence the modification which I have ventured to term "supra-condyloid amputation"—an operation which, retaining the advantages of Gritti's method, eliminates its defects by lengthening the anterior flap, forming a posterior flap one-third in length of the anterior one, suturing the patella and femur together; and, lastly, and most important of all, by making a high femoral section, but one not involving the medullary canal.

The special advantages that may be claimed for supra-condyloid amputation are:—

1. That the posterior surface of the anterior flap being covered with a natural synovial membrane, the chances of suppuration and purulent absorption are diminished.

2. Any possibility of the split patella shifting from its place on the cut surface of the femur is prevented by the high femoral section, and by suturing the two bones together.

3. The vessels are divided at right angles to their continuity, and not obliquely, as in other flap operations.

4. The existence of a posterior flap diminishes the chances of any wide gaping of the wound; while the anterior flap, being oval, increases the chances of the stump tapering toward its extremity and assuming the form of a rounded cone.

5. The preservation of the normal attachments of the extensors of the leg.

These advantages embody those of both flap and circular amputation of the thigh, and at the same time eliminate their defects.

In concluding an address so admirable that we regret our inability to give it in full, the speaker said, "I have mentioned many achievements in surgery the past half century has witnessed. Fifty years hence this great Association will, I hope, meet here again, to celebrate its centenary."

Prague as a Medical Centre.

Dr. Roswell Park, of Chicago, writes to the *Medical Bulletin* concerning the superior advantages which Prague offers to Vienna for the *finishing* studies in medicine. There is a maternity hospital in which 3000 confinements take place annually. Gussenbauer (a former pupil of Billroth) he esteems fully as able a surgeon as his former teacher, while Hasner, the oculist, is the most rapid operator living, and Lanfall he considers fully as good an aurist as either Gruber or Politzer. Besides, there are only about one-fifth as many students as in Vienna, which affords better opportunity for study. Since Prague lacks the reputation of Vienna, the fees for the courses are much less, living is less expensive, and the surroundings are quieter, less distracting and much more conducive to study.

Tri-State Medical Society.

The eighth annual meeting of the Tri-State Medical Society (Illinois, Indiana and Kentucky) will take place in Terre Haute, Indiana, September 26th, 27th and 28th. The President is Dr. J. M. Holloway, of Louisville, Ky; Secretary, Dr. G. W. Burton, of Mitchell, Ind.; Treasurer, Dr. F. W. Beard, Vincennes, Ind. Dr. J. E. Link, of Terre Haute, is Chairman of the Committee of Arrangements, and Dr. Wm. Porter, of St. Louis, Mo., Chairman of Committee on Programme. The programme that we have received indicates that the meeting will be both an interesting and an instructive one, there being no less than fifty-three reports and addresses to be made.

American Academy of Medicine.

At a recent meeting of the Council, the annual meeting of the Academy was postponed until October 26th (Thursday), when it will take place at Philadelphia, at the time of the Bi-centennial Celebration in that city.

Medical Service in the British Army.

From the *British Medical Journal* we learn the following particulars concerning the organization of the medical department of the British force in

Egypt. The force ordered to Egypt consists of about 36,000 men. For this number of soldiers the grand total of those connected with the medical department is 1746 officers and men, 304 vehicles and 940 horses.

Cremation in France.

The Minister of the Interior in Paris recently received the officers of the Society for the Propagation of Cremation, and listened to their arguments. It was his opinion that cremation could only be practiced under the sanction of a special law, and he promised not to oppose the passage of such a law.

Items.

—The National Board of Health of Germany last year spent nearly four million dollars in the prosecution of their labors.

—Prof. Botkin, in Petersburg, celebrated, on April 27th, his jubilee. He had been twenty-five years a successful teacher.

—Dr. I. N. Evans, of Montgomery, who served in the Forty-fifth Congress, is a candidate for the Republican nomination in the Seventh district.

—Sir Edward Burrowes Sinclair, the highly esteemed obstetrican and gynecologist, and a well known writer on subjects connected with his specialty, died lately in Dublin.

—We read from the Vienna papers, that as director of Duchek's Clinic, in Vienna, Professors Erb, Eulenburg and Nothnagel—all three from Germany—will be proposed by the Faculty.

—The latest news in the great field of antisepsis may be considered the fact that the sinews of the Kangaroo are now employed instead of catgut, for ligatures and sutures. They are said to possess none of the disadvantages, but all the benefit, of all other animal sutures, being especially reliable in the ligature of large vessels and in the suture of wounds. (*Deutsche Medicinal Zeitung*, III, 16, 1882.)

—In the beginning of this year blood was withdrawn, for the purpose of a transfusion, from the arm of a fifteen-year old boy, without consent of the parents. The boy himself removed the bandage, and acted otherwise contrary to the directions of the physicians. Mortification set in, followed by death. The parents instituted proceedings against the doctor, but were non-suited, as the boy, not obeying the instructions, became alone responsible for the result. An appeal has been taken to a higher tribunal, and we will communicate the decision in time.

—More than one thousand deaths are reported as having resulted last year, from accidents in mines of the United Kingdom of Great Britain and Ireland. The average of such deaths during the last eight years is one to every 464 persons employed. Fall of rock from the roofs, but more particularly from the sides of the workings, continues to be the most fruitful source of these disasters, and there seems good reason to believe that a large proportion might be prevented by a sufficient provision of timber supports.

—At the last meeting of the Academy of Sciences of Paris, the President, M. Jamin, announced that a committee had been formed some time before to present the eminent chemist and biologist, Pasteur, with a medal commemorative of his great discoveries in those sciences. On the committee were the names of Dumas, Tisserand, Davaine, and many others well known in scientific and social circles. After an able and eloquent *résumé* of Pasteur's special labors, the medal was handed to that distinguished *savant* by his old friend and master, Professor Dumas.

OBITUARY NOTICES.

DR. WILLIAM H. MUSSEY.

Dr. William H. Mussey, of Cincinnati, died in that city July 31st, 1882. Dr. Mussey was one of the most distinguished and public-spirited citizens of Cincinnati. He was born in Hanover, N. H., Sept. 30, 1818; studied medicine in the Ohio Medical College, and was graduated Doctor of Medicine in 1848. He subsequently studied eighteen months in Paris, and upon returning to this country settled in Cincinnati, where he made a specialty of general surgery. He was Vice-President of the American Medical Association in 1864, and afterwards Vice President of the Ohio State Medical Association. He also held various eminent positions in hospitals and colleges. He was commissioned Brigade Surgeon October, 1861, and Lieutenant-Colonel and Medical Inspector of the United States Army in June, 1862, and was surgeon-General of Ohio for several years. He was also President of the Natural History Society of Cincinnati.

DR. CARLOS CARVALHO, U. S. A.

Dr. Carlos Carvalho, assistant surgeon U. S. A., died near Boston, July 23d, 1882. He was a son of Emanuel Carvalho, who represented the Chilian Government at Washington for many years. He leaves a widow, formerly Miss Emma Bayliss, of Washington, and two young children.

DR. NATHANIEL FOSTER.

Dr. Nathaniel Foster, an old and eminent physician of Cincinnati, died July 16th, of paralysis. He was a brother-in-law of the late Gen. W. H. Lytle, and was well known throughout the Union.

QUERIES AND REPLIES.

Old Subscriber, Wisconsin.—Bandaging, passive motion of the joint, kneading and friction, with the internal use of iodide of potassium, may do some good, though such enlargements are very obstinate and do not yield readily to treatment.

J. H. S., California. Your description is too vague to enable us to recognize the disorder which you term "moth." If you refer to tinea versicolor, the best treatment would be one of the sulphur preparations, applied locally.

S. T., Nevada.—We never heard of a case where acids produced such an effect.

W. H. J., Ohio.—Croton-chloral is formed by the action of chlorine on allyl. It is an anæsthetic.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

DIAGNOSIS AND TREATMENT OF BENIGN TUMORS.

BY GEO. HALSTED BOYLAND, A.M., M.D., ETC.,
Of Baltimore, Maryland.

A tumor, as the word signifies, is any swelling. But from this broad definition practical wants have led to the very many divisions, subdivisions and classifications that crowd our exhaustive works on surgery; indeed, this one subject not only claims more space than any other in them, but whole works are published continually on tumors as a class, or even on any one kind of tumor. Certainly this is perplexing. It is our aim, therefore, in the present article, to place before the general practitioner such condensed information on the subject of benign tumors as may be useful in ordinary practice.

Under the term new growth, foreign growth, in its widest sense, are comprehended all those foreign processes that take place in the human body; either by cell formation, or by precipitates and concretions out of the liquids. The latter possess no texture; these are mostly stones and irregular concretions. On the other hand, we may readily recognize a regular structure and texture in the first named, which, in chemical relation also, claim for them the designation of "organic;" moreover, they offer a long list of common characteristics, which in many respects are entirely independent of the tissue or part in which they appear.

These organic new growths fall, of themselves, into two groups, benign and malignant, principally the former claiming attention in this paper. In spite of the great variety of organic new growths, they all resemble each other in one respect, and that is, that they are composed of the same morphological elements that we find also in the healthy body, and develop themselves on the same plan of construction as normal tissue. In the arrangement and length of development of their elementary principles, the different new growths vary perceptibly as well from normal organs, as from each other. It is upon this and upon the different texture of the pseudoplasma that the distinction above named founds itself, of which more anon.

It is of great importance, theoretically as well as practically, that the morphological elements of new growths can be subject to the same changes as those of the normal organs of the body—namely, the so-called regressive metamorphosis; the fatty, colloid, amyloid degenerations, the mucous softening, the chalky (lime) and bony processes. The chemical composition of new growths shows no marked differences from that of normal tissue.

Albumen, fibrin, cheesy matter, fat, further, substances that give lime and cartilaginous lime on boiling, pigment, also the ordinary salts, cooking salt and phosphate of lime, and finally, water, in greater or less quantity, have been with certainty demonstrated, by chemical analysis, to exist in tumors. In tumors we often find widening and tearing of the blood vessels that run through them, therefore, also, bleeding, inflammation, ulceration and gangrenous disturbance are also found.

Ætiology.—The general ætiology of new

growths is very dark. As local cause, only a certain irritation of the diseased part can be considered. As regards predisposition, it may be noticed that new growths are not unfrequently inherited; sometimes they are on the patient when born; again, they are at other times endemic or epidemic. Predisposing are also early youth and old age, overwork and insufficient food, also other disturbances of the general system, brought about by former diseases. But to return to our two groups—embracing all tumors known—benign and malignant.

From a practical standpoint those tumors are benign which rest upon purely local causes and interfere with certain functions only by pressure upon or pushing aside organs. They can entirely stop the action of an organ, and thus become harmful to the individual, even, perhaps, threatening life, but do not at all exercise any evil influence directly upon the general system. Finally, they remain circumscribed in the locality where they sprung up, and do not return after extirpation. In distinction from these we designate as malignant tumors, those that continually and steadily grow, and finally soften (break down); that successively appear in different places and different organs; that return upon the same or other places after extirpation (recidiration), finally, that develop a marked and general affection (cachexia), and most always bring death to the individual suffering from them.

To the first belong fatty tumors (lipoma), sebaceous tumors (steatoma), fibrous tumors (fibroma), the different skin tumors (cysts, lupiæ) and bone growths (exostoses); vascular tumors (aneurisms, varices, telangiectasis), also polypi, cartilaginous tumors (enchondroma), that first became distinguishable by microscopic research, and were earlier mostly classed under the so-called steatoma, but only on account of their consistency and outward appearance. The representative of malignant tumors, from Hippocrates down to the present day, is cancer (carcinoma), so that malignant and cancerous are still used as synonymous. The fungus medullaris can be only technically a distinct or separate form of cancer; its origin being a hardened mass (scirrhus). Sarcoma is also included, and the tubercle, that formerly belonged to inner medicine only, in the category of malignant neoplasms.

Diagnosis and Treatment of Fibroma.—The diagnosis of fibroma is not without difficulty. Fibrous tumors can be confounded with other hard tumors, or even some soft ones; in many cases it is, for instance, difficult to say with certainty whether the tumor is more of a fibrous or sarcomatous nature. The diagnosis, by a due regard to the tough, stringy or knotty consistency of the tumor and its hardness, must be our main *point d' appui* in excluding other growths, such as enchondroma, osteoma, cavernous tumors, cysts, cancers and sarcoma. Fibrous tumors, like other benign ones, do not possess the tendency of malignant tumors, to soften from the centre out or to soften in different places. As opposed to malignant tumors, fibroids never cause disturbances of the general system, and generally never other disturbances than those of purely mechanical origin and corresponding to the size and locality of the tumor. Swelling of the adjacent lymph glands is absent, except when it is occasioned by inflammation of the tumor. Emaciation and loss of strength are also absent, as a rule, but can develop when the tumor by its position, by ulceration or hemorrhage of its ulcerated surface, produces disturbance of the general system. The only *treatment* of fibroid tumors consists in operative removal. In general, thorough and complete extirpation with the knife is the best; nevertheless, if the seat and relations of the tumor admit it, other means of separation may be advantageous—écrasement linéaire. Chloroform may be given. Prof. Nathan R. Smith used a little chloroform in the extirpation of a fibroid tumor of the breast, in a young colored girl. I had the pleasure and honor to assist him, at his request, in this operation. The patient, a young woman, was about 18 years of age and well nourished, otherwise perfectly healthy, menstruating regularly. The tumor was situated in the left breast, movable and hard. The Professor grasped the tumor at its base and made the incision along the upper surface with a scalpel, and in the long diameter, while I held the edge of the wound and took up the arteries. The operation lasted but a very few minutes; no sutures were used, the edges of the wound being secured by adhesive plaster, and the patient making a good and rapid recovery. The tumor was about the size of a turkey's egg. There was nothing peculiar about the case, but it is a good, typical one, illustrating the ordinary facility with which fibroids may be removed, and a guarantee thus given against return; and it further gives some idea of Prof. Smith's views upon the administration of chloroform during surgical operations. When the girl asked to be thoroughly narcotized, he replied, "I do not want to put you into your last sleep." We gave her, accordingly, a partial narcosis only. In the history of a given case of fibroid we will generally find the growth of the tumor has been slow and without pain.

Diagnosis and Treatment of Lipoma.—Fatty tumors develop themselves almost entirely at an advanced age. The acceptance of the diathesis lipomatosa theory is not warranted by practical observation. The etiology is dark. A blow, push or knock may cause them. They grow slowly and without pain to the patient, whose first inconvenience from them is felt when they attain a large size. To the hand they feel like lumps of normal adipose tissue, that can be pushed aside, and have always a certain tough resistance. The diagnosis of this particular kind of tumor is comparatively easy. Pharmaceutical treatment almost useless. Extirpation is the only radical cure, and this should be done as early as possible. If the tumor has attained the size of a nut or of a hen's egg, or is growing in such a manner as may be seen from day to day, then the operation should be performed at once, as it is very simple, and certain success always follows it at this period, while longer delay invariably brings some dangers. But if the base of the tumor has already considerably passed the size of a hand, then it is better, as a rule, not to operate; because such a lipoma left to itself has never death as a consequence, while an operation that would leave a wound surface of such extent, even undertaken in the most favorable conditions, may endanger life. If the tumor threatens to break through the skin, the operation should be performed, under almost all circumstances; also when the seat of the tumor endangers life. The extirpation of fatty tumors requires great care. At times it is impossible to remove all parts of a lipoma. But even if we remove the most of it we have accomplished much, and it is pretty well established that pieces left behind neither become the germs of larger tumors nor interfere in any way with cicatrization.* In the case cited by Burow,† who extirpated an enormous growth of this class, weighing 27½ pounds, it was impossible to remove the whole tumor. "The healing of the wound took place with incredible rapidity, although large pieces of the still remaining lipoma died in the wound and sloughed off." Considerable hemorrhage may occur, but this is exceptional. If the patient is knife-shy, the écraisement linéaire is in order, but the galvano-caustic wire is much better, and prevents effectually hemorrhage from smaller vessels. Sometimes it is possible, after making an incision in the skin, to isolate and tear out a lipoma with the fingers, by pulling the tumor toward the operator with one hand and pushing back the skin from around it with the other.

Diagnosis and Treatment of Enchondroma.—The cartilaginous tumor forms a round mass with smooth or slightly nodulated surface, that can attain different sizes; sometimes very large size. The commencement may be only as large as a pea, and can take place wherever cartilage exists in the body (Virchow). Not infrequently these tumors, later on, become ossified. They generally cause little trouble beyond pressure, and can exist for from fifteen to twenty years as harmless tumors. The chemical examination of enchondroma has determined that they give chondrin as their main principle. As regards their etiology they often date from earliest childhood, and I. Müller notes especially that the mechanical influences of life and the process of formation of bone during childhood are the first causes of abnormal cartilaginous growth. As far as my own personal experience is concerned I have generally seen them on the fingers and toes. One case of great interest merits a line in this connection. It was that of a young man of about 25 years of age, who had enchondroma of the size of black walnuts on all the fingers and toes of both hands and both feet. Operation was, of course, not thought of, and the patient, who lived in a small German town (Juebingen), came periodically to Baun's clinic, where I was practicing at the time, to be exhibited to physicians and students, more as a surgical curiosity than anything else.* Enchondroma feel hard to the hand, and their diagnosis on the living is not always easy. Even when they are situated on the periphery, and are thoroughly cartilaginous, they have a resistance that resembles that of bone; they feel as hard as stone, ivory-like, as a scirrhus of the breast or a true bony tumor (exostosis). This is exceptional, however. They generally possess a light, glandular, warty surface, of large size, and the nodules on the periphery appear to roll themselves inward, and not to go over directly on to the base of the tumor (soft parts or bones). Exostoses, on the contrary, have a smooth or jagged surface, and spread evenly on all sides in the bone substance. The differential diagnosis is more difficult as regards fibroids, as enchondroma can develop themselves, not only in soft parts, but also on bones, and sometimes *inside* bones, and for this reason can be covered with a bony capsule outwardly, formed by pushing up the bone from within.

* Lebert. *Abhandlung der practischen chirurgie*, p. 119.

† Burow. *Deutsche Klinik*, No. 24.

* In this case the tumors were situated on the last rows of phalanges, at the joints.

The only successful treatment is operative. Even this is not always advisable, unless the tumor, by its position and size, interferes with the function of important parts or threatens danger from expectant breaking out. According to its position, the extirpation may be made by the knife, or with saw and chisel, or we may amputate the part upon which the growth sits. The experience of Dieffenbach in this respect is very valuable, that even after partial extirpation cicatrization can follow. The ossification of pieces of enchondroma left in the wound is regarded as fixed.* If part of the tumor is soft, if it is combined, or is a cystochondroma, we can never count upon anything but a total extirpation. If large arteries run through an enchondroma we may have great difficulty in arresting hemorrhage, in making a partial extirpation, as it is impossible to get hold of the vessel with the pincette, to tie it. As it lies imbedded in the cartilaginous substances, our only recourse is cautery with the iron (actuale); even this does not always suffice. The galvano caustic would be more likely to meet our wants here than almost any other method.

The Diagnosis and Treatment of Exostoses naturally follows, just as enchondroma may become exostoses; and these latter pathologically have the same distinguishing features as enchondroma. We have a soft, porous, spongy exostosis, a hard, ivory-like exostosis, and osteo-cartilaginous exostosis. Exostosis can exist on any bone. It is usually of slow growth, and the soft parts covering such a bone remain healthy. There is no pain during the earlier stages of growth, or even later, unless the exostosis, having attained a very great size, presses severely upon the soft parts, when inflammation may follow, bringing ulceration of the skin, and this in turn succeeded by laying bare the exostosis. Rokitansky and Nélaton attribute the ending in necrosis only to the hard, smooth, ivory-like growth (exostosis eburnea), probably on account of the great dearth of canals for the blood vessels—Haversian canals. Any of the forms of exostosis may become inflammatory, suppurative and carious. They probably rest upon a dyscrasia, or are often hereditary. There may be only one, or many, and on different parts of the body. There is but little more to be said as regards the diagnosis of these immovable, hard, jagged, or smooth, bony tumors—in so far as palpation is concerned; there is less that will aid us in making a diagnosis of exostoses if they cannot be reached by the hand, on account of lying deep and being covered with soft parts; for if undoubted exostoses do not exist on other parts of the body, and thus lead us on the right track, we may as justly attribute the functional trouble to a tumor of another class. In comparison with enchondroma, the surface of an exostosis is smoother, less nodulated, but often sharp, like a cock's comb. The treatment of exostosis is always difficult, sometimes dangerous, often useless. We may only expect results from antiphlogistic and anti-dyscrasic means, when we have to do, not with a true exostosis, but with an osteophyte still in process of formation; that is, with an inflammation of the bone or periosteum. True exostosis can only be removed by surgical operation. If its position is such that the operation would be more dangerous than the further growth of the tumor, it should be left untouched. If the patient desires an operation on account of deformity, or great pain, or interference with the use of parts, it may be performed, provided there is no special danger. Nevertheless, no matter what plan is adopted for the removal of an exostosis, there are all the dangers of a deep-seated suppuration, with affection of the bone to follow; osteo-myelitis, ending in pyæmia, after simple removal of an exostosis, has been frequently observed.

The operation for exostosis consists: 1st, in sawing off, *i. e.*, extirpation of the tumor; 2d, the employment of actual cautery; 3d, resection of the part of the bone on which the exostosis sits; 4th, amputation of the part affected. The ordinary operation, that is, the one that the general practitioner will oftenest have to perform, consists in laying bare, fully and freely, the exostosis by a long incision, the skin being held back by hooks, one on either side, in the hands of an assistant; the tumor is then sawed off with the saw, chain saw, or removed by chisel and hammer, care being taken to hold the chisel well down, parallel to the bone. In vascular, spongy exostoses, with broad base, the best method is the pereum caudens, as it gives us a guarantee against profuse bleeding. Only under these circumstances should actual cautery be employed in the removal of exostoses, as it always causes a partial necrosis, followed by inflammation and suppuration. In order to prevent this, it has been proposed to lay bare the exostosis, carefully scrape off the periosteum, and leave the rest to nature. Necrosis of the upper layer may be, of course, expected after this, but it is extremely doubtful if the whole tumor could be sloughed off in this way. Osteoma of the soft parts must be extirpated like other tumors.

Diagnosis and Treatment of Telangiectasis,

* Lebert. Loc. cit.

Fungus Vasculosis, Nævus.—These are mostly congenital, sometimes caused by a blow, push, or pressure. Mostly on the outer skin; they may, however, appear on mucous membranes; for example, on the lips. Diagnosis generally easy. They may exist on all parts of the body, varying in color from a bright red to a dusky purple and dark brown, in size from a pin's head to that of a black walnut. They have been mistaken for epithelioma, aneurism, lipoma and varices, but these are extreme exceptions, not likely to be met with in general practice; the characteristics of the tumors mentioned being usually so very marked as to make a mistake difficult; besides, they belong to a more advanced period of life. The forehead is often chosen as their seat. Simple angioma is never malignant, even though local recidiration may occur after incomplete extirpation. My plan is to let a nævus alone, unless it grows rapidly. From the long list of therapeutical and operative measures, the following will be found most useful: Compression by bandage, application of cold and astringents (Abernethy). If the tumor is a very vascular one, ligature of the artery leading to it, thus preventing further engorgement of the veins, the primary cause of telangiectasis (and to it these tumors owe their softness when touched by the hand), also are recommended, the introduction of a seton, the hypodermic injection of perchloride of iron (Carter has seen death caused by embolism after this; it is, nevertheless, endorsed by different authorities);* further, the actual cautery, and cautery by medicaments—chloride of zinc. I tried the lapis infernalis in one case—the nævus, a small red speck resembling a broken vein, upon the cheek of a little girl about four years of age, at first increased in size and then began to diminish, and is now disappearing, about the fourth week after the cauterization. They will often do this, however, if left to themselves. Concentrated nitric acid applied on the point of a pine stick, is probably the most effectual caustic. If we have a medium-sized and soft warty tumor (nævus), with pedicle, we may pass a silk thread around and strangulate it—cauterizing the wound surface left with argent nit. (lapis). Sir William Ferguson ran two long needles through the base of a nævus; these were armed with silk thread and were passed through, the one horizontally, the other perpendicularly; the four ends of the threads left projecting after the needles were withdrawn were then tied together and the nævus thus cut off. If the tumor is a fungus hematodes, the following application will act very well:—

℞. Potas. iodid., Aquæ, āā ℥j. M.

This makes an excellent caustic, and will speedily check the advance of the tumor, if applied every day or two as occasion requires, and continued for some time. If the telangiectasis is of a cavernous kind, filled with either blood or lymph, palpation will give us valuable points, especially as regards fluctuation. If opened, the cavern should be swabbed out with a small sponge, wet with a solution of carbolic acid and glycerine, in equal parts, and dressed with adhesive plaster. Great care should be exercised if the diagnosis reveals a cavernous tumor. The galvano-caustic is here, above all, the most sure method, and the one that will give the best results.

Diagnosis and Treatment of Glandular Tumors—Adenoma.—The diagnosis of adenoma is readily arrived at from hyperplasia of a gland, on which it always sits. Almost all that has been said with reference to healing tumors by operation and pharmaceutical means holds good here, only we may obtain better results with medicaments and compression in adenoma, than in other tumors. One remarkable case that came under personal observation, was that of a man in middle life, whose left breast being affected with adenoma, had swelled to the size of that of a girl of sixteen years; the nipple was regularly elongated, the tumor soft to the touch and altogether like a normal female breast. No treatment was given, as the tumor had become stationary and was not objected to by the patient.

Polypi.—Medium hard, bright red or yellowish growths, mostly on mucous membranes, from which they hang by a stem. They are covered with cylinder-epithelium externally; toward the centre they present a mass of thickened mucous membrane, having its origin in a hypertrophy of the minute slime or mucous glands. The cause of their formation is usually to be found in chronic catarrhs, and the nose seems to be their first choice. They are of slow growth, and only cause annoyance by a sense of pressure and fullness in the upper part of the nostril, where their stem allows them to slip up and down, and where they may be easily felt and seen, both from the outside and within. Removal is the only cure. This is quickly, easily and safely accomplished by means of a pair of pincers. The patient, seated in a chair, should be made to expirate, by which the polypus will descend a little, when it is firmly

* Bardeleben-Chirurgie, Vol. I, p. 428.

grasped with the instrument and torn out. The operation is attended with but insignificant loss of blood, and as regards after treatment, nothing is necessary. Very rarely we find one at the top of the pharynx, which if of a more compact structure, will be best removed by galvano-caustic.

Sebaceous tumors, cysts, skin tumors, etc., are such growths as are contained in dermoid, round sacks, closed on all sides, the contents being usually either serum or a composition of fat and lime. The sack itself is a part of the tumor. They may also be formed by the encysting of foreign bodies, such as a gunshot or bullet. They are often due to a tendency to fatty degeneration, but little, however, is known about their general etiology. They feel hard and immovable to the touch, are painless and of slow growth. I will select one case out of my own practice as illustrative: G. G., aged 35, male, well developed and healthy, consulted me three years ago about what he supposed to be a shot left in the lobule of the ear from the discharge of a gun. Upon examination I told him it must be a shot, as it felt exactly like one in point of size and consistency, and as he had a gun discharged at him, other shot having taken effect at the time. Last month he consulted me again, as I had declined previously to interfere. The tumor was softer, but still right hard to the touch, and had grown to the size of a bird's egg. I operated, making the incision behind the lobule of the ear, in order to conceal the scar, and extirpating sack and all. The wound was dressed with adhesive plaster only, and healed rapidly per primam. On opening the sack no shot was found, only sebaceous matter. Operation with the knife is the only radical cure in these cases. A hygroma or ganglion may be punctured, and its contents thus emptied; fluctuation and softness, without inflammation, make them easy to diagnose.

A BIT OF CLINICAL EXPERIENCE AT THE OBSTETRIC BEDSIDE.

BY T. CURTIS SMITH, M.D.,
Of Aurora, Indiana.

The obstetrician often meets with cases in labor that need considerable well-directed tact and discrimination to enable him to do the right thing at the right time, and in the right way, for his patient, and also to acquit himself creditably. Sometimes a case needs a good dose of morphia, sometimes a strong oxytocic.

At the time when the discussion as to the oxytocic powers of quinine and the cinchona salts was active, several years ago, I often tried their virtue in tardy cases of labor. Was called about 3 A.M. to a lady who claimed to be having uterine pains. Her time for confinement was fully up, and she had experienced a few sharp contractions. Examination disclosed a wide, open os, very flaccid. I waited an hour. Only two light pains. Os still the same. The lady stated that I need not be in any haste, as she was always two to three days in labor, and this was not in any way different, so far, from previous experience. I considered the history given, and also recognized a state of almost complete inertia. Gave her at once cinchonidia sulph., grs. x. In twenty minutes there was a severe contraction. This was followed quickly by another and another. In thirty minutes from the time she swallowed the cinchonidia she was fully delivered, and the uterus well contracted down. She had a good recovery. I have often repeated this kind of practice in similar cases, and almost always with prompt benefit.

In 1878 I was called to a lady who had, in her first labor, a very tedious siege. Her pains affected her head, and would come and go in the temporal region with quite perfect regularity. The uterine contractions were feeble and ineffectual. What her attendant gave her I do not know. In this, her second labor, the pain was again in the head, as before. I found her to be a feeble woman, much worn down with her previous sufferings. She was thin, pale, pulse feeble, and greatly depressed, pupils dilated, uterine contractions very feeble, extremities cold, os dilated. She begged me not to give her any morphia, as she would "almost die of the nausea that would follow its use." I gave her, however, morphia sulph., gr. $\frac{1}{8}$, cinchonidia sulph., grs. x, at once, and used a hot mustard foot-bath. In half an hour the head was much relieved. A few minutes later the uterine contractions increased in force and regularity. In one hour more she was delivered. After the uterine contractions became fully normal there was no further complaint about the head. She had a good recovery and no nausea or vomiting from the morphia. A few weeks ago I was called to see a lady in whose case the liquor amnii had been drained off for sixty hours, and there had not been a single uterine contraction of any considerable force. The case had been in the hands of a midwife. Examination disclosed an open, flaccid os, lax uterine walls, and a first vertex presentation. The lady seemed as well as though nothing whatever was unusual about her condition. I gave her cinchonidia sulph., grs. xx, in three doses an hour apart. In a short time feeble uterine

contractions came on. These rapidly increased in force until the delivery was quite rapidly completed. I might detail many cases more or less like these, and where cinchonidia or quinine seemed to be of great utility, and to act with great promptness in stimulating uterine contractions.

On the other hand, there are many cases of labor where the pain is very severe, but there is not a corresponding uterine contraction; hence the pains continue to come on for hours without manifesting any expulsive power. Often a full dose of morphia will settle this needless distress, and the contractions will come on normally and labor proceed to a fairly happy conclusion, or the pains will cease altogether and allow the patient a more or less prolonged respite before labor is fully inaugurated. These cases may call forth a separate paper at another time.

In April, 1878, I was called to see a large, healthy lady, in her ninth labor. She was suffering intensely with headache; face flushed, pulse hard and full, pupils contracted, light painful. The uterine pain was light and irregular. I ordered potass. brom., ℈j, every two hours, with also gtts.ij of fl. ext. aconite root, hot mustard foot-bath, and an enema, which cleared the bowels quite freely. Left word to call me at once if there was an increase of head pain, or if labor demanded attention. I feared convulsions, and believed venesection the right practice; but as it was so heavily condemned I desisted for the time. Eight hours later was called. All the suffering in the head greatly intensified and symptoms aggravated. I then tied up the arm, bled her twenty-four ounces before the pulse showed any signs of softening down or the face to lose its turgid flush. She at once lay down and slept two hours, when she was awakened by a sharp labor pain. In one and a half hours she was delivered of a healthy girl. Never had a head pain or untoward symptom after venesection was practiced.

Some years ago I was called to see Miss H. She was expecting confinement, but thought her time not yet out. She was suffering intense headache; face fairly turgid and head throbbing, skin hot, pulse hard and full, urine scant, bowels slightly constipated. Tied up her arm and bled her until the stream ceased of itself; then opened another vein and did likewise, securing in all not over a pint of blood. Gave a full dose of magnes. sulph., which operated freely. She was relieved, went a full month, and was confined by a midwife without an untoward symptom.

Mrs. B., aged 28, third confinement, a woman of strong muscle, a hard worker, full habit, taken in labor at end of her full term. The contractions were very severe, the os rigid, pulse bounding, skin hot, some little headache. The rigid os was the greatest obstacle to free delivery. After four hours of active uterine contraction and the os still unyielding, the arm was tied up, and she was bled until there was a little softening of the pulse, and a little less flushing of the face. Then, almost immediately, dilatation permitted the rapid conclusion of a previously tedious labor.

I well remember an almost fac simile of this case that occurred to me in 1867. The conditions were the same. I had not the courage to bleed the woman. Prejudice was very strong against it, and I was young and timorous. For thirty-six hours the woman continued in active labor (with an unyielding os and perineum), before it was completed. I firmly believe that a free venesection would have set matters right in a little time.

I cannot, by any means, be considered a strenuous and demanding advocate of venesection. But I believe, in properly chosen cases of labor and of threatened eclampsia, and in some cases where eclampsia is already fully developed, it is the very remedy of all others needed. It is to be used as discriminately as we would use any other powerful remedy or means in contest with disease. Never used hap-hazard. Thus brought into requisition it will assume its rightful place in therapy, and be found of great utility.

I reported some of these and similar cases verbally, to a medical society of which I was a member. To my surprise some of the gray heads present thought the treatment was very good, but exceedingly daring for this day and age of anti-depletion. Now, if it was good practice, why call it daring? I had and still condemn myself for not resorting to direct depletion earlier in these cases.

It is certainly to be hoped that, while we should never adopt indiscriminate venesection, as in the past, we may, however, adopt it with that same careful discrimination with which we administer and apply other potent agencies in the treatment of diseases.

—The well known chemical inventor, Jean Wickersheimer, in Berlin, has now invented three fluids, which, while doing no harm whatever to the substances, protect bread, meat and beer against all influences of temperature, weather and atmosphere, for many years.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM GOODELL, M.D.,

Professor of Clinical Gynecology.

Reported by Wm. H. Morrison, M.D.

STRICTURE OF THE RECTUM—PROLAPSE OF THE WOMB.

Gentlemen:—I had expected to bring before you, to-day, a case of complete laceration of the perineum, but she has disappointed us. Menstruation has kept away one patient and the bad weather has kept away another, so that we shall have to take what we can find.

The first is a woman whom I have not seen. She is 42 years old and has had several children. Her labors have all been of a natural character.

Five years ago she began to have difficulty in defecation. This has gone on from bad to worse, until she now passes her fæces in ribbons and with great difficulty. Dr. Baer has examined the rectum and found a stricture.

While the woman is being etherized let me say a few words in regard to difficulty in defecation.

I received a letter a week ago, from a physician, in reference to a patient who had previously consulted another physician on account of some difficulty in defecation, which commenced some months ago, but as she gained no relief she consulted the gentleman who wrote to me. He told me that on examining her he found what he thought to be a tumor, but whether it was in the substance of the vagina or an outgrowth of the womb he could not say. This tumor, by its pressure on the rectum, caused the difficulty of which she complained. The way he managed the case was by insinuating a rectal tube above the tumor and injecting the rectum in this way. The woman came to my office this morning. I examined her, and felt a tumor through the posterior wall of the vagina. I think that it is a cyst in Douglas' pouch, which has grown from the under surface of the broad ligament, and being unable to ascend, has developed below, and so pressed upon the rectum as to obliterate its canal. I shall aspirate this tumor after the lecture, and expect to find fluid.

Ribbon-like fæces, with mucous casts of the rectum, sometimes occur in bad cases of retroversion. In retroversion the womb is hypertrophied, and is apt to press upon the rectum, obliterating it to a certain extent. We then get ribbon-like fæces, and in addition, these mucous casts of the bowel. These are very interesting, but have not as yet been thoroughly explained. In these cases, supporting the womb, rest, and a building-up, constitutional treatment will usually overcome the trouble. Arsenic, under such circumstances, is very good.

There is another form of obstruction which I wish you to bear in mind. That is, hysterical obstruction. It is very common. I do not know that a month passes without my having such cases on my hands. I will explain it to you. A woman is hysterical; she is nervous; she has spinal irritation; there is an irregular circulation of the blood and nervous fluid. When I am nervous, I blush or I grow pale, through the influence of emotions on my nerves. The hysterical woman, from the condition of her body, mind and cerebro spinal nervous system, blushes and blanches internally. She blushes in her spine, or some other internal organ, and there is too much blood; or (I am carrying out the simile, and it is a good one) she blanches in these organs. As a result of this action we get spasm of the sphincters. If you push me, and want to know how these changes produce contraction of the sphincters, I admit that I do not know. I only know it as a clinical fact, as I know that calomel will cause purging. The best treatment for this condition is a tonic treatment, with rest, massage and electricity; but in the country you cannot fully carry this treatment out, and have to rely upon tonic and neurotic remedies.

There is still another condition in which you have ribbon-like fæces passed, that is, in fissure of the anus. This woman suffers considerable pain, but not enough to lead us to suspect a fissure, which is a common thing in woman, for, as I have often said, where one man has a fissure, ten women will have one, as a result of constipation. These fissures are very irritable, and excite spasmodic contraction of the sphincter, causing the fæces to be passed in ribbons or in little pellets. By the way, in nervous women, in whom there is no apparent sphincteric contraction, fæces will be passed in the form of pellets.

I shall now examine her. I notice, in the first place, that she has a little prolapse of the posterior wall of the vagina. I observe one thing, which is an evidence of a prolonged labor; she has no cervix uteri. She is only forty-two years old, and the cervix is usually not obliterated until much later. In some severe labor the vagina, which is attached about half an inch above the os, has been stripped all the way down to the mouth of the womb, and in this way the cervix disappears. In such cases it is difficult to support the womb with a pessary, as we cannot get behind the neck of the womb. She has also had a bad tear of the perineum, but this has united.

Passing the sound into the cavity of the womb, I obtain a measurement of only 2.5 inches; trying again, I obtain the same result. This is due to the atrophy of the cervix but it is rare; even in old women, to find this condition.

At the mouth of the meatus we have what looks like a small carunculus, but on closer examination it proves to be a polypus.

I shall now examine the rectum. Before making this examination it is always well to rub soap under the nail. I feel the stricture very distinctly, and the question arises, is it syphilitic? is it a result of natural causes, or is it cancerous? As she has had it for five years, it is not at all probable that it is cancerous.

These cases of stricture are very liable to be complicated with recto-vaginal fistula. You would suppose that when a woman had a stricture, with obstruction and great distention of the bowel above, the fistula would be above the

stricture, but this is not the case. In the majority of cases the recto-vaginal fistula occurs below the stricture. This is due to the fact that a small quantity of fæces finds its way through the constriction into the pouch below, sets up irritation, causes ulceration, and we have an opening into the vagina. These are very troublesome. A short time ago, I received a letter from a lady, and to show you how much patients will sometimes blame their physicians, I will tell you about it. This lady's story was that she had a stricture of the rectum. She had been treated for some time, but a recto-vaginal fistula resulted. The only inconvenience it produced was a whistling sound, resembling that made by a toy balloon. Her family physician, not succeeding in closing it (he applied nitric acid and nitrate of silver), she consulted a noted surgeon (she does not mention his name), who made an incision from the fistula through the perineum, but it did not heal up. I cannot find any fault with this, for I did precisely the same thing myself last spring, but fortunately, in my case, the parts healed up, excepting a very trifling fistula. The lady says that the surgeon put no sutures in, and she adds, "you can imagine my horror when, after getting up, I found that I had one vast opening from the vagina into the bowel." She has no control over her bowels, and a constant bearing-down sensation. She has had three different operations performed, but with only partial benefit. The lady may be mistaken in saying that no sutures were put in, for patients will exaggerate. In my case I did put stitches in, and I think it would be wrong not to do so.

What shall I do with this case? I do not know her history, but as many of these cases depend on syphilitic disease, I shall give her a tonic preparation of mercury, which taken for a few weeks, will do no harm. I shall give her minute doses ($\frac{1}{24}$ of a grain) of the bichloride of mercury, and if I find her blood poor, I shall also give her iron, and perhaps arsenic.

If a woman has had venereal disease, and you are certain that the recto-vaginal fistula depends upon that disease, there is no earthly use in attempting to close the fistula until you have expelled the disease (if that can be done) from the system.

I propose to dilate this stricture. What is the danger in dilatation? First, the force employed may be sufficient, in the diseased state of the bowel, to burst through it into the peritoneal cavity. This is a very serious matter, and in the great majority of cases results in death. That is one reason that I do not like to get hold of these cases. The careful introduction of my index finger may cause a rupture of the bowel. Such cases, as I say, usually die. Why? Because the fecal gas, and sometimes the fæces, pass into the peritoneal cavity, causing peritonitis.

The next danger is hemorrhage, so high up as not to be easily controlled. (While I am talking I shall go on and break up some of this mass.) This is not a pleasant complication. Suppose, gentlemen, that I had a bleeding that I could not readily control. I should then use injections of vinegar. I wish you to remember the hæmostatic qualities of vinegar. It is one of the very best in post-partum hemorrhage, because it can always be obtained. It is also excellent in all operations on this part of the body. For instance, you are scraping a cancer of the cervix; the bleeding obscures vision; you inject vinegar and the bleeding is checked.

I must confess that, from my examination, I cannot tell whether or not this is malignant. It certainly looks cancerous. I am going to leave pieces of this here, and ask some of those gentlemen who are investigating these new growths to examine them and give us their report. There is another thing; there is considerable hemorrhage, more than I like to have under the circumstances. This also leads me to suspect that this is malignant.

Suppose you have tried in vain to check the hemorrhage with vinegar. You then try Monsel's solution and it fails. You must bear in mind that you may have bleeding and death, without the apearance of blood externally. After the injections have failed, take a silver female catheter, or an elastic catheter, and tie around it, below the eye of the instrument, a small petticoat, a circular piece of muslin. That forms an umbrella, so to speak. You then pass the catheter into the bowel until the eye gets beyond the stricture. You then pack between the muslin and the catheter, thus expanding the umbrella. The object of the catheter is to allow the gases to escape. After plugging the rectum a set of nervous symptoms appear, and wind is formed very rapidly. If the woman cannot pass the wind the abdomen becomes very much distended, she becomes very uncomfortable, and you have to remove the plug.

I can now pass my finger with ease through this stricture. I shall now wait a few minutes, to see if there is an internal bleeding. If there is I shall stretch the sphincter, have her carefully watched, and if necessary have the rectum plugged.

At one point I have gotten all the way through the bowel. I want to be sure that I have not gotten into the peritoneal cavity. I examine with my finger, but I cannot pass it beyond a certain point. The sound gives the same result. What I feel may be the posterior layer of the peritoneum. There is still one point at which I want to scrape the rectum. I shall do it very carefully, so as not to get into Douglas' pouch anteriorly. I have never yet gotten into the peritoneal cavity while performing this operation, although I am always afraid of it. It is astonishing how easy it sometimes is to burst through the bowel.

If this is malignant (and the fact that I have been able to break it down so easily, and its whole appearance, would indicate that it is) what I have done will be merely of temporary benefit. Having gotten through the friable surface this bleeds less profusely. It is like cancer of the cervix, when you begin to scrape it you have a great deal of bleeding, but if you push on boldly, going down to the firmer tissues below, the bleeding usually stops. I have now a very good opening.

I shall stretch the sphincter a little, so as not to have any accumulation of blood. Now, there is an advantage of her being in the hospital. If this were a private patient I should certainly inject

some astringent, but being in the hospital, where she can be carefully watched, I shall use no injection.

She will now be taken to the ward. We shall give her enough opium to allay the pain.

Prolapse of the Womb.

This is the patient I had before you last Wednesday, and on whom I performed a preliminary operation. I shall not perform the second operation to-day, but shall send her home to recuperate from this operation.

You will remember that it was this unfortunate woman who had a complete prolapse of the organs of generation. The womb was entirely outside of the body. On examining her to-day, it looks as if the womb was still projecting from the vulva, but it is only the posterior wall of the vagina. We are paying attention to that ulceration which you see there. We are using boracic acid on it. Iodoform would do very well, but it makes such an abominable smell. The formula for the ointment which we are using is as follows:

℞. Pulv. acidi boracici, ℥ ij
Glycerinæ, ℥ j
Vaselinæ, ℥ j. M.
Ft. ung.

This is a very excellent healing ointment.

The operation I performed last week was upon a tear of the neck of the womb, which was probably the original cause of all the trouble. There was a bilateral laceration of the neck of the womb; this arrested involution; the womb remained larger and contained more blood; having more blood, it was plastic, it could be elongated. There being also a tear of the perineum, the vagina prolapsed, pulling down the bladder and the uterus.

The next operation will be one leading to the support of the womb wholly within the body. I have not decided what operation I shall employ; perhaps the one lately devised by Le Fort.

To-day I intend to remove the stitches. I shall leave two stitches in, to support the parts. The womb has remained up for two reasons: first, it has been, to a slight extent, shortened by the operation, and second, she has been lying on her back for a week.

We shall keep her here until the parts are sufficiently healed, and then send her home to recuperate, for by that time she will have been in the hospital for a considerable period. (The patient was then removed.)

Now, gentlemen, let me tell you the reason why I send her home. I had a very analogous case on which I operated before you three or four weeks ago. I performed at that time the operation for cystocele. I removed an elliptical-shaped piece of the mucous membrane of the anterior wall of the vagina, and brought the edges together. They united perfectly. Two weeks later I restored the perineum, which had been ruptured. That also united perfectly. The very day before I intended to remove the sutures she was suddenly seized with collapse, became cyanotic and had violent dyspnœa. Her condition was explainable only on the supposition of septic poisoning, or of heart clot. The action of the heart was so tumultuous that I could obtain no information from the heart sounds. I then decided the question from the temperature. I said to myself, "if this is septic poisoning, there will be a temperature of 104°, 105° or perhaps 106°." The nurse took her temperature, and found it only 97°. I then took the thermometer and made the observation myself, with the same result. The inference then was that it was a heart clot. Whether the heart clot had been produced by a previous rheumatic condition, whether deposition of fibrin had taken place during two prolonged operations, in which ether was employed, or whether the clots were due to a depressed condition of the blood brought about by a long stay in the hospital, I cannot say; but she died, and I do not wish to put this woman in jeopardy of her life from an operation usually so harmless.

I shall send her home and have her return after the holidays, for the second operation.

Editorial Department.

Periscope.

Chronic Inflammation of the Ovary.

This miserable condition, for the relief of the numerous symptoms and sequelæ of which removal of the ovary has been practiced, has caused this operation to be much discussed pro and con. One of its principal advocates is Mr. Lawson Tait, and he has been much criticised. Therefore, an article by him on the subject, in the *British Medical Journal*, is very opportune. We may have acute or chronic inflammation of the ovary. Acute inflammation is often fatal, and when not fatal it generally leads to a state which makes life-long misery. The acute disease may originate in a simple chill, in a hæmatocele, in an attack of gonorrhœa, in some exanthematic fever, or in miscarriage or child bed. The last two sources are by far the most common. Many cases recover and leave no mischief behind, but in others the permanent mischief gives rise to terrible suffering. The symptoms of the acute form are very vague. Oftentimes a woman will say that since she had smallpox, scarlet fever or acute rheumatism, she has never had her periods as she used to have them. For a time more profuse, they became subsequently scanty and painful, the pain increasing as time went on, lasting sometimes for a week or more in every month, rendering her miserable and relieved only by narcotics. We examine the pelvis and find, perhaps, nothing at all. She has received all kinds of guess treatment, and continues to suffer at intervals till the climacteric period is passed. The chronic form offers more definite symptoms. The majority of these cases occur in primipara, therefore, it is noted that the patient has had one

child soon after marriage, and has never been pregnant since. It uniformly unsexes the sufferer, as far as maternity is concerned. They are rarely free from pain, which is intensified during the menstrual week. There is always pain in the left groin, for if only one ovary is affected it is sure to be the left. In many cases a fixed and tender mass, composed of the enlarged and probably adherent ovary, or of the occluded and distended tube, will be felt on one or both sides of the uterus, through the vaginal *cul-de sac*, and the peculiar sickening pain produced by touching the mass will prove its nature. The treatment is the same as that of inflammation of any other organ. But no treatment is of much avail, according to Mr. Tait, other than the extirpation of the organ. He says:—

"Removal of the inflamed uterine appendages may yet turn out to be a failure for some cases; but it never can be so bad as the removal of an eyeball for cancer; and, in the hands of experienced operators, the operations have quite an equal risk. Besides this, the operation for the removal of the uterine appendages is as yet in its infancy; we have very much to learn about it; yet, in spite of this, in my hands, of thirty-five cases performed for chronic inflammation, there has only been one death, or a mortality of 2.85 per cent—a mortality which, I have some reason to believe, is less than that of excision of the eyeball. This one death was due to causes entirely preventable, and ought not to have occurred. The operation is justified by its primary success; and my belief is that my mortality, as my experience grows, will not be more than one or two per cent.

Precisely the same kind of argument applies to its secondary results, which, in the hands of inexperienced operators, are admittedly bad. For my own results, so far, I have abundant cause for satisfaction; some of my cases are yet incompletely relieved, but by far the majority of them are absolutely cured. The first patient from whom I removed an ovary for pain, nine years and a half ago, was completely relieved of symptoms, and she remains so to this day."

Pseudo-hypertrophic Paralysis in Four Brothers.

Dr. Donald Macphail records these instructive cases in the Glasgow *Medical Journal*. In all the disease commenced at about the same age, when the boys were about six years old. The onset was marked in the very beginning by a shuffling walk, an apparent inability to raise the foot well from the floor in walking, with a liability to trip and fall over trifles. From this slight beginning the cases progressed until, in that of the oldest boy, there is almost complete loss of power of the lower extremities. The appetite and general health keeps good. The muscles are very much wasted.

The mother is aged 46, is strong and well developed, and has "never had an hour's sickness." She has a large circle of relations, among whom such a thing as paralysis or fits of any kind has been unknown.

The father is supposed to be about 55. He is suffering from paralysis of the lower limbs. I have not been able to see much of him, but the history and symptoms, so far as I know them, seem to point rather to "descending sclerosis" of the spinal cord. There is marked rigidity of the lower limbs, a certain degree (increasing) of contraction, and very marked shooting pain and severe twitchings, which often awaken him at night. He is unwilling to admit that the disease has been present for more than twelve and a half years, but his wife states that he halted slightly and tripped easily before their marriage, and that he steadily but very slowly became worse. The progress of the disease seems to have been hastened by a hurt received from a fall of stone in the coal-pit where he worked about twelve years ago. His relations have all been healthy.

There have been nine children in the family, six boys and three girls. Four of the boys are accounted for above. Another boy, aged 16, a miner, has been affected a year and a half with symptoms similar, I am told, to those seen in the father, viz., lameness, most marked in the right leg, slowly increasing stiffness, flashing pains, and marked twitching. I have only seen him once, however, and only for a few seconds. The remaining brother died, aged 9 years, of dropsy and "disease of the bowels." Of the three sisters only one is alive, aged 21 years; she has always been strong and healthy. One was drowned, aged 8 years, and the other died at the age of 4 years, of scarlet fever.

The Amyloid Kidney.

The study of all amyloid degenerations is always an interesting one. Here we have to deal invariably with a known cause, producing the degeneration simultaneously in several organs, and we can follow up the process from its beginning throughout all its stages. Dr. E. Wagner has investigated 265 cases, and published the result of his researches in the *Deutsche Arch. f. Klin. Med.*, xxxiii, p. 416.

The causes which in these 265 cases led to the amyloid degeneration of the kidneys were as follow: phthisis 136; diseases of the bone, not syphilitic 56; syphilis 36; diverse rarer diseases (bronchiectasis, chronic ulcerative skin affections, chronic diseases of the mucous membranes, of the same nature, empyema, pyelitis pyelocystitis, parametritis, psoas abscess, cancer, sarcoma) 36; without detectable cause (no dyspepsia, based upon amyloid degeneration? Ref.) 7. Regarding their morbid anatomy, four different varieties may, according to Wagner, be recognized, possessing also some clinical importance.

(*a*) Amyloid kidney without alteration of the epithelium and the stroma.

(*b*) With fatty degeneration of the epithelium, but uninjured stroma.

(*c*) With fatty degeneration of the epithelium and fresh interstitial alterations.

(*d*) Amyloid-atrophic kidney. This form happens mostly in syphilitic persons, and is caused by amyloid degeneration of a previously atrophic kidney.

In twenty cases, in which the urine had been more or less frequently examined, the latter was

as follows: quantity mostly decreased, rarely normal or increased at the beginning of the disease. Spec. grav. generally 1.012–1.020. Color usually light and clear. Percentage of albumen medium. Sediment sparingly or absent; if present, pale. Tube casts often for days absent, broad forms very rare. Only twice amyloid reaction demonstrable on the tube casts. The latter hyaline or fatty degeneration and frequently covered with white corpuscles. Twice casts with myelin drops; once epithelial casts. In one-fourth of the cases red, in half of them white blood-corpuscles. Mostly sparingly granular detritus.

Dropsy was not an extraordinarily frequent symptom, but when present, remarkably obstinate. Several times uræmic vomiting. Ten times hypertrophy of the left ventricle, but, we suppose, then with atrophy of the kidneys.

Hypertrophy of the Heart.

Dr. Bryan Charles Waller contributes to the *Medical Times and Gazette* a lecture on this subject, from which we extract the most salient points, since it will be well for the physician to have them ever before him. Though a pathological change, in that it involves an appreciable deviation from the normal standard, it is not by any means, of necessity, an unfavorable condition. On the contrary it is traceable, etiologically, in the majority of instances, to a secondary attempt at compensation by augmentation of the *vis a tergo* for some primary lesion involving obstruction to the circulation. Such hypertrophies are by no means confined to the heart. Examples of hypertrophy from constant use are to be seen in the blacksmith's arm, and the well developed calves of mountaineers and ballet dancers.

With respect to the ultimate tissue elements, a hypertrophy may be either simple or numerical. In the former, the size of the original elements is increased, their number remaining constant; in the latter, both size and number are alike augmented.

Rindfleisch believes that the muscular fibres undergo multiplication by a kind of splitting process. If we refer to the normal histology of the myocardium we shall see that the muscular fibres divide and branch, forming a sort of network, composed of thicker strands giving off a number of thinner ones. If we suppose that at the point where a muscular fibre divides, it further cleaves downward from the point of bifurcation, we can easily conceive how a numerical multiplication may be thus affected. This view receives some support from the fact that small longitudinal slits and fissures may be occasionally seen extending downward from the bifurcation, as if the fibres were about to split further. Each one of these fibres might grow to the size of the parent and again bifurcate.

This view is rendered probable by the absence of apparent increase in the diameter of the fibres of hypertrophied hearts, which is affirmed by many observers, and corroborated by the results of my own experience.

Concerning concentric hypertrophy, he considers its existence as a pathological condition, very doubtful, and says: I should accordingly advise you provisionally, and in default of further evidence, to include concentric hypertrophy of the heart in the list of post-mortem changes due to tonic contraction at the moment of death, in which position it becomes fixed by cadaveric rigidity. Though rare, and often not a little puzzling, from an etiological point of view, primary or idiopathic hypertrophy does certainly exist. But far more common than the primary hypertrophies are those which are secondary to some antecedent obstruction or hindrance to the circulation of the blood, or the motions of the heart. Let us again suppose a case of aortic stenosis. Before the development of hypertrophy there will be anæmia in front of the stenosed orifice, that is to say, in the aorta and all the arterial portions of the general systemic circulation. But in addition to this, there will also be mechanical engorgement behind the obstructed orifice. Thus, *firstly*, the left ventricle and auricle; *secondly*, the pulmonary veins, capillaries and arteries; *thirdly*, the right ventricle and auricle, and *fourthly*, the venæ cavæ and their branches, will be engorged with blood which cannot make its way fast enough through the partially closed aortic opening. The blood will stagnate in the lungs, and will no longer undergo thorough aeration. But if the left ventricle now hypertrophies, all these grave conditions will become modified for the better. This cavity will then work double tides; the aortic anæmia will be corrected, and the block behind will be relieved; the blood will no longer stagnate in the lungs; the right ventricle will again possess an unembarrassed outflow; and the engorgement of the great veins will subside.

A second class of intra-cardiac obstructions which are relieved and modified by secondary hypertrophy are those caused by dilatation of a heart-cavity. A cavity thus dilated will be obviously burdened with a greater fluid dead-weight. This state of matters will affect the circulation in much the same way as stenosis of a valvular orifice. The dilated cavity will contain more blood, while its propulsive power is, at the same time, diminished; and arterial anæmia in front, with mechanical engorgement behind, will again result. Hypertrophy of the dilated cavity will render it capable of propelling the additional dead-weight of its fluid contents, and thus the circulatory conditions will again approach their normal standard. Many such dilatations are due, in the first place, to regurgitant valvular disease.

I would have you observe that in obstructive valvular lesions, hypertrophy usually occurs directly, and without intermediate dilatation; while in the regurgitant conditions it almost always follows on a previously developed dilatation. This difference is explicable on the ground that the primary dilatation is principally due to forcible entrance of blood during diastole, while the primary hypertrophy is merely caused by the necessity for overcoming the direct obstruction of stenosis.

Very remarkable examples of eccentric hypertrophy of the ventricle are furnished by those cases where aortic stenosis and insufficiency are co-existent. The insufficiency permits diastolic regurgitation, with consequent dilatation, while

the stenosis prevents complete emptying of the ventricle during systole, until a perfect hypertrophic compensation is established. Thus, before compensation is complete, the ventricle is never entirely empty, either during systole or diastole. The resulting enlargement is often enormous. Such a heart is that which I now show you. The aortic orifice is stenosed, and the valves are incompetent. The left ventricle is greatly hypertrophied, and the heart in its recent state weighed one pound eleven ounces.

Statistics of Amputations.

From an elaborate statistical report of the amputations performed in the Glasgow Royal Infirmary during eight years ending December 31st, 1882 (*Lancet*), we extract the following salient points:—

These statistics show a considerable decrease in the rate of mortality after amputations, for the eight years under consideration, as compared with similar statistics for the previous twenty five years. Thus in the first period the number of amputations was 1412 and the deaths 452, giving a mortality of 32 per cent. In the last eight years the amputations were 726 and the deaths 166, equal to 22.8 per cent., showing a decrease of nearly ten per cent.

The number of primary amputations was 307 and the deaths 98 or 32.3 per cent., against 659 in the previous twenty-five years, with a mortality of 36.5 per cent., a decrease of 4.2 per cent.

	Cases	*Deaths*	*Or*	*Against*	
Shoulder joint..	36	13	36.1	39.3	per cent.
Arm.....	68	14	20.5	33.5	"
Forearm.....	28	2	7.1	11.6	"
Hip joint.....	3	2	66.6	85.7	"
Thigh	47	22	46.8	52.5	"
Leg	42	11	26.2	44.9	"
Ankle joint.....	26	6	23.0	27.5	"
Foot, partial...	7	0	...	20.0	"
Elbow joint.....	1	0	...	50.0	"
Knee joint.....	25	13	52.0	40.0	"
Multiple.....	24	16	66.6	57.0	"

The mortality of the four primary major operations, which are usually referred to as the test of success, was as follows: In 185 cases 49 deaths, or 26.4 as against 35.8 per cent.

The number of secondary amputations after injuries was 81 with 27 deaths, or 33.3 as against 51.7 per cent.

The number of amputations for diseases was 338, the deaths 40, or 11.8 against 21.9 per cent. No special cause could be assigned for this decrease in the rate of mortality.

The Segmental Nature of the Spinal Cord.

The *Lancet* says, editorially, that the spinal cord may be regarded as composed of a series of segments, indicated by the pairs of spinal nerves. According to Lüderitz, this view of its structure is morphologically correct. The spinal cord of the ringed snake shows a slight rounded swelling opposite each pair of nerves, which lies above the junction of the respective vertebræ, and consequently corresponds in height to the middle of a segment. The enlargement is due chiefly to that of the gray substance, but partly also to that of the white and to an increased size of the so-called lateral group of cells. The demarcation between the segments cannot be exactly determined, but they are longer in the middle of the cord and shorter toward the extremities, especially toward the basal portion. Similar segmental swellings are to be discerned in the spinal cord of the rabbit, even on naked-eye examination. Careful microscopical measurements of the areas of the several constituents of the cord in transverse section show an analogy between these elemental segments and the swellings of the cervical and lumbar enlargements. The middle part of each segment, for instance, bears a similar relation to the extremities of each segment when the area of the constituent columns is compared. The increase in size at the middle of each segmental swelling is greater in the transverse than in the antero-posterior diameter. The gray substance is enlarged in all directions, but especially in width. The spinal cord of man, however, presents no segmental swellings, and its elements can only be recognized by the intervals between the series of nerve-roots which arise from it. These intervals are larger between the posterior roots than between the anterior, and they are the greater the longer are the segments, being greatest in the middle and lower dorsal regions.

Sclerotinic Acid.

Sclerotinic acid is a substance without taste or odor, feebly acid and hygrometric, but not deliquescent. It has been obtained from ergot by MM. Dragendorff and Sodevissotzky; good ergot containing about four or four and one-half per cent. of the substance. In their experiments on frogs they found that subcutaneous injection of half a grain caused almost complete paralysis, commencing in the hind limbs; there was no reaction on irritation; the cornea was insensible; from time to time a feeble cardiac contraction was noticed. This state persisted for some days; then there was slow amelioration; finally a fresh attack of paralysis, followed by death.

In 1879 Nikitin published a very complete work on the physiological and therapeutical action of sclerotinic acid.

The principal symptoms observed by experimentation on various animals were paralysis, diminution of blood pressure and of the contractile force of the heart in cold-blooded animals.

In acute poisoning he found diminution of temperature up to the time of death, gradual slowing up of respiration, which underwent complete arrest before the arrest of circulation in fatal cases, and finally augmentation of the peristaltic movements of the intestine. From many experiments, Nikitin concluded that sclerotinic acid induced uterine contractions, whether the organ was gravid or not, and rendered the contractions stronger when they already existed.

As regards the therapeutical action of the substance Nikitin recommends the employment of sclerotinic acid, in the dose of three grains, to produce uterine contraction. He has never observed tetanic contraction of the uterus under its use. The mortal dose in the adult is about one hundred and fifty grains.

Among other observers, opinions regarding the therapeutical value of the drug are widely divergent. Hobert, who first administered it, obtained no beneficial results from strong doses in pulmonary hemorrhage or hemophilia.

Ganguillet found that strong doses (fifteen grains) augmented the duration of uterine contraction during labor; this result was obtained about half an hour after the administration of the drug; he gave the acid in an equal quantity of powdered sugar. Rennert injected the acid subcutaneously and obtained results which he considered inferior to those obtained from the use of ergotin. Professor Prevost, of Geneva, has used this substance in metrorrhagia from fibromatous tumors, and considers it as active, if not more so, than ergotine. Stumpf asserts having obtained good results in various forms of hemorrhage, and recommends the employment of strong doses. The observations are, it must be said, as yet, too few to pronounce definitively on the therapeutical value of the drug.

Reviews and Book Notices.

BOOK NOTICES.

Diseases of the Rectum and Anus. By Charles B. Kelsey, M.D. Wm. Wood & Co. (Library of Standard Medical Authors.)

We consider this to be one of the best numbers of this series. It is a carefully prepared monograph, not twenty or thirty years old, but up to the times and fresh from the hands of the author. He has made himself well acquainted with the literature of the subject, and his own experience has been ample enough to enable him to form an independent judgment when authorities conflict. We have read, for instance, with a great deal of satisfaction, what he says about the disputed point of the value of carbolic injections in piles, and think he expresses the case fairly and on good grounds. So we might add of other subjects, that his conclusions usually impress the reader as fair ones and based on sound observation.

The International Encyclopædia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery. By Authors of various Nations. Edited by John Ashhurst, Jr., M.D., Professor of Clinical Surgery in the University of Pennsylvania. William Wood & Co. Vol. II, p. 754.

The contents of this volume are as follows: "Contusions," by Dr. Hunter McGuire; "Wounds," by Mr. Thomas Bryant; "The Antiseptic Methods of Treating Wounds," by Mr. W. Watson Cheyne; "Poisoned Wounds," by Dr. John H. Packard; "Sabre and Bayonet Wounds," by Dr. J. H. Bill; "Gunshot Wounds," by Dr. P. S. Conner; "The Effects of Heat," by Dr. T. G. Morton;" "The Effects of Cold," by Dr. J. A. Grant;" "Abscesses," by Mr. Howard Marsh; "Ulcers," by the late Dr. John T. Hodgen;" "Gangrene and Gangrenous Diseases," by Dr. E. M. Moore; "Gonorrhœa," by Dr. G. W. White; "The Chancroid," by Dr. F. R. Sturgis; "Syphilis," by Dr. A. Van Harlingen; "Venereal Warts, etc.," by Dr. H. R. Wharton; "Surgical Diseases of the Skin," by Dr. James C. White; "Diseases of the Cellular Tissue," by Dr. Joseph W. Howe; "Injuries and Diseases of the Bursæ," by Dr. Charles B. Nancrede.

The names of these writers are sufficient guarantee that the articles are accurate, that they present the art of surgery as it is understood by the most alert students to-day, and that each topic is discussed as fully as the amount of space permits the writer. At the same time, it is inseparable from this plan of getting up a book, that there should be some exhibition of contradictory theories, and some presentation of personal preferences. Thus Mr. Cheyne's article on the antiseptic method of treating wounds must be pronounced an ardent and narrow defence of Prof. Lister and his method, as if they were the only representatives of the aseptic system. Prof. Halford's ammonia treatment of snake bite certainly merits at least a statement of what it is, but Dr. Packard, in his implied condemnation of it, does not even give it that much attention.

A good share of the volume (from page 324 to page 600) is taken up with the articles on the various venereal diseases. These are all deserving of a great deal of praise, as they are compact, clear and practical.

The articles on gunshot, sabre and bayonet wounds have been prepared after careful inspection of the immense mass of new material collected during our civil war, and also after a study of the extensive collections in the National Medical Museum and Library. They are, therefore, peculiarly complete and authoritative, and present results which, as yet, have not become as well known as they should be.

In Dr. Morton's otherwise satisfactory article on "The Effects of Heat," we felt some surprise that he made no reference to sunstroke. It is quite as appropriate, in a surgical discussion of this subject, as lightning stroke, which he does give.

The editor makes some allusion to the "artistic excellence" of the illustrations, but we candidly confess they disappoint us. As a rule they do not "come up" well. Probably this is due to the printing or to the finish of the paper. There are several lithographic plates, which are only fairly well executed.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE PREVENTION OF EPIDEMICS.

The outbreak of yellow fever at various points along the Gulf Coast, both in Florida and Texas, is a salutary warning how constantly our country is exposed to this terrible scourge. We have no guarantee but that any summer may witness, in New York, Cincinnati or St. Louis, the terrible scenes which history records in Philadelphia in 1793 and 1819, and in Norfolk and Memphis within the memory of all adults. Sanitation does not arrest the progress of this pestilence, nor is altitude a safeguard against it.

It is a permanent menace, and let it once secure a foothold in the populous and filthy slums of the great cities we have just named, and no one of them will escape under a sacrifice of millions of money and tens of thousands of lives.

What is the preventive measure? In spite of all that has been said, we believe in but one—Quarantine. Of course, modern hygienists of a certain school maintain that quarantine is ineffectual, even harmful. But much of the opposition to quarantine arises from its conflicts with "business interests." These interests will at all times cheerfully sacrifice the life of the masses to the greed of the few. These interests are thoroughly selfish, always ready to falsify health returns, always preferring to involve a State rather than endanger their own petty monetary gains.

This is why we have no great faith in the wisdom of Dr. HAMILTON'S recent announcement that, as Chief of the Marine Hospital Service, he would not declare a port in quarantine except with the consent of the local authorities. Perhaps he has no authority to go beyond this. He probably has not. In that case his position is regretable, as he ought to do that which the limitations of his position prevent him doing.

Local boards are not willing to acknowledge the presence of yellow fever until it is a fact too patent to be denied. Then they usually insist that it is of a mild type, and that segregation is needless.

Medical authorities are not always exceptions to this rule. It would be nowise difficult to name recent instances where the presence of contagious diseases in towns and cities has been concealed or denied by medical officers. They offer plausible reasons, as that the public would be needlessly frightened, that business men would suffer, etc.

Such are the difficulties which an effort at efficient prevention must always meet with. The power to declare quarantine ought to be lodged in a strong central body, a federal office, which would act for the good of the whole country, even if it did require heavy sacrifice of some single localities.

CONGRESS AND THE NATIONAL BOARD OF HEALTH.

We wonder whether the time will ever come when the average human being will give evidence of possession of that seemingly rarest of attributes, "*common sense.*" No one, we take it, who belongs, and ought to remain, outside of a lunatic asylum will think of denying the eminent truthfulness of the old saying that "an ounce of prevention is worth more than a pound of cure,"

yet there are comparatively few men who demonstrate by their acts their professed belief in this axiom. The recent action of Congress in cutting down the appropriation to the National Board of Health to such a ridiculous figure that it will hardly suffice to pay office expenses, is one of those seemingly unaccountable acts of man that can only be explained by the assumption that those who thus legislated lack common sense, howsoever brilliant may be their qualifications as statesmen. We fear not contradiction when we make the statement, that of all bodies in this country, the National Board of Health is by far the most important and the most necessary to the material welfare of our country. We know that health is wealth, and we know, equally well, that wealth is useless or valueless without health. The National Board of Health was created to conserve the national health, by preventing the entrance and spread of disease-producing causes; here, in brief, is the object for which this body exists: It cannot fulfill its mission without money, and by this recent congressional act it has been so crippled as to make it almost practically useless. It is impossible to attribute this lack of interest in matters pertaining to sanitation to other than two causes. Either genuine ignorance of the importance of such preventive measures and the wonderful results they are capable of accomplishing, or to a want of common sense among our law makers. We fear the latter is the cause, since no one can, to-day, plead a genuine ignorance of the value of sanitation when the public press, and the medical profession are constantly presenting its importance to him. It has been stated by the Health Commissioner of one of our most prominent cities that this action on the part of Congress has grown out of the "jealousy of New York, whose health authorities are opposed to anything which will cut down the fees of the Health Inspector there, and New Orleans, whose people object to having a national inspector stationed at their port, lest he might tell the truth about yellow fever and so hurt the business of the city." If this charge be true it only goes to prove that those into whose official care is given the health of their neighbors, also lack this great virtue, since they have defeated the very measures that their positions ought to teach them are so very essential to the carrying out of sanitary reforms. It is a crying outrage for our people to allow their representatives in Congress to appropriate foolishly large sums for *great jobs*, and to refuse to make adequate provision for the preservation of the health of the land. The country doctor is usually an authority in his neighborhood in matters political as well as medical. Let us urge such to take some action in this matter. Explain to your patients the necessity and value of an efficient national board to each and every inhabitant of the land. The intelligent ones will be all the more ready to believe what you say, because they will understand that what you are advocating is in reality opposed to your own pecuniary interests, and that you are therefore actuated purely from a sense of duty, from a regard for the obligations that every man owes his neighbor. At election times seek out the delegates to primary and county conventions, and urge upon them to support only such candidates as are willing to pledge themselves firmly to a liberal support of this Board. It is needless, and would be an insult to your intelligence, to tell you how much good can be accomplished by the well-directed action of health boards; but one fact in this connection is so striking as to be worthy of note. One hundred years ago the annual death rate in England was more than eighty per thousand. Health boards and sanitary associations were unknown. Since then well organized sanitary associations have gradually been brought into existence, with the result that the death rate is now only about eighteen per thousand. The *people* of this country are commencing to take an interest in and realize the value of sanitation, and are ready, if directed how so to do, to compel their representatives to so legislate that they may be protected from the inroads and ravages of disease. This instruction should and must emanate from the medical profession. Their teaching prepares them in an especial manner to appreciate what grand results can be achieved in this direction, and if they fail to so inform their patients they

are neglecting a great and paramount duty that is continually staring them in the face.

THE CAUSE OF DEATH.

We know, almost for certain, how death takes place in all fatal diseases; *i. e.*, we say, that an individual dies, either by the brain, heart or lungs. In reality, however, we are still ignorant how death is brought about, how the machinery comes to a sudden stand-still, what extinguishes, with the last flickering of the final expiration, the vital spark forever. The brain may be extirpated, and animal life has been observed to be still going on; the heart may apparently cease beating, and yet the existence of the being is not finally ended; respiration is to all appearances not filling and emptying the air vessels any more, but still more than vegetation keeps up the complicated machinery, the spark of life still lingers.

What, then, is it that finally causes death? Does it not look very much like the sudden action of a powerful poison, which so thoroughly and at once disintegrates the great circulating, life-giving and life-preserving fluid, the blood, that the nerve centres end their existence, and force the organism to cease every motion, like an engine deprived of its steam?

Experiments that have lately been made, and which we have to thank for the discovery of the *Ptomaines*, may tend to lead us a step further in the solving of the question before us. A. Gautiér has made these ptomaines a special study. It has been demonstrated that many organic substances, the fibrin in the blood, the urine, and certain compounds of tissues, when decomposing, give rise to alkaloids—called ptomaines—which are powerful poisons. This discovery we owe mainly to Selmi. But Gautiér has done more. He thought that if such alkaloids are formed on the decomposition of organic substances, why may not, in the course of the common change of tissues, if the latter is deviating from its true course, also such ptomaines be called into existence.

The result of these investigations fully confirmed his theory. A disciple of G. Pouchet succeeded in obtaining from the normal urine a fixed and easily crystallizable alkaloid, the hydrochloric compounds of which crystallize, as well as those with gold chlorid. and platinum chlorid. And this alkaloid has been found to be exceedingly poisonous; in most minute doses it causes stupor, tetanus and death, within the shortest time imaginable, stopping the heart in systole. This very quality relegates this alkaloid of the urine to the ptomaines, for the toxic effect of which the stoppage of the heart in systole is most characteristic. A mixture of ferrum-chlorid. and ferro-cyanide of potassium colors this alkaloid blue, as it does all ptomaines. Gautiér was able to isolate from the poison of two poisonous snakes (Trigorrocephalus and Naja) two similar alkaloids.

Gautiér proved also the intensely poisonous action of the human saliva on birds. He evaporated twenty grms. of saliva in the water bath, dried the 0.25 grm., weighing residue, and dissolved it in warm water. This solution injected into a small bird, under the skin, caused stupor, dilatation of the pupil, increased frequency of respiration, and in all cases, death. He was able to isolate an alkaloid also out of the human saliva. This alkaloid gave the same color reaction as the other ptomaines.

Another characteristic quality of these ptomaines is, that they form salts with most of the vegetable alkaloids, as morphia, codeia, atropia, veratria, aconitia, hyoscyamia, eserin, and others. The ptomaines are very easily oxidizable, and may be formed during the normal change of tissues, even without the presence of oxygen.

What may all these investigations, and their astonishing results, not explain? If a hypodermic injection of some vegetable alkaloid accidentally is made into a larger vein, and a fatal result the consequence, under all the symptoms which we used to ascribe to the entrance of air, may not the real cause of death be found, perhaps, in the sudden formation of these poisonous animal alkaloids? May not many other similar occurrences, which to-day are clouded in mystery as yet, find a similar interpretation? May not, at the time of the dissolution of the body, a similar

process turn out forever the flame of life? Is it urea, in uræmia, that causes the fatal uræmic symptoms, or does the presence of urea in certain quantities, and under given conditions, produce the formation of these highly poisonous animal alkaloids?

The subject is one of great interest to the medical profession. We mentioned in one of our late numbers, when speaking of the pure keratin prepared from the eggshell-membrane, and its easy transformation into leucin and tyrosin, the "multum e parvo" of nature, and here we have a still more glaring proof, with what few means nature—as with the magic touch of the mystic wand—achieves the greatest results.

THE DARK AND LIGHT AGES.

One cannot read the addresses delivered at the recent meeting of the British Medical Association, without realizing how dark must have been the age of medicine fifty years ago, when viewed from and contrasted with the almost dazzling brilliance of the present age of enlightenment and progress. The past fifty years have been, so far as we know, unprecedented in the medical history of the world, for wonderful progress, undreamed-of achievements and most beneficent developments. It is true that many of the arts of to day are, as Wendell Phillips so beautifully tells us in his famous lecture on the "Lost Arts," but revivals of the realities of bygone ages, and that many accomplishments familiar to our far-back ancestry seem to us but as the mythical impossibilities of a wonderful imagination. Viewed from this standpoint it might seem possible that some ages long past have been equally favored with the comprehensive knowledge that goes to make up the science of medicine that is vouchsafed to us of to-day. But when we remember that we have absolutely no record whatsoever of any such state of knowledge, we are perforce compelled to believe that in our science the present age is by far the best informed and the most progressive in the world's calendar.

Again, it would seem, in the light of the developments of the last half century, that during that period more real progress has been made than in all the many years that had elapsed before. True, isolated discoveries of signal importance have been from time to time made public and proven by experience, but in no other period of medical history have so many and so various additions been made to our knowledge. Every branch of our science has advanced with the most rapid strides. Physiology, histology, pathology, diagnosis, therapeutics, all, indeed, seem as though they had only been heard of fifty years ago, so much do we know now, and so little (comparatively) did our fathers then know. Operations commonly performed to-day would have seemed to them but little short of murder. This progress is but a part of the general march of the world in all scientific pursuits, which has rendered this century a notable one. In this general march any one can have a part, and all should take an active interest. Remember that the life of man has a limit, and that while a large corps of unusually intelligent investigators are now busily employed in unraveling the hidden mysteries of the normal and pathological life of man, the time will come when the dreaded hand of death will summon these men from their earthly labors. If their places are not filled by equally capable men, science will suffer, the dark age will gradually steal back upon us, we will lapse into stagnation, and all that has been gained by the lifelong labors of these grand men will be practically lost, insomuch as it will not be utilized to teach us more. Therefore every one who can (and this means absolutely every one) should constitute himself an investigator. He should cultivate the habit of minute and constant observation, should remember and reason upon that which he observes, and when he has reached some practical result from his meditation, make it known. We must all help to keep rolling this mammoth ball of progress; each must contribute his mite toward the lever that will ultimately succeed in lifting and firmly planting our science on the solid and impregnable foundation of an *exact* science. Remember that many of the greatest discoveries in medicine have been made by country physicians; so let those who imagine

that their country residence debars them from the advantages of experience and observation enjoyed by their urban confrères, disabuse themselves of this erroneous idea, and taking courage from these few words, set to work, each one determined to add his quota to this general, universal medical progress.

PARENTAL GOVERNMENT.

How providential the care is which the Prussian government takes of its subjects, may be guessed from the following: As is well known, in Berlin, as well as in other great cities on the continent, there exists horse-slaughtering houses. The meat is sold to be eaten by persons who may like it, or who buy it because it is cheaper; and it is also mainly made use of to feed dogs. But to prevent any unhealthy meat being sold, and to be able to follow up any possible infection or to detect any infringements, as well as to protect its citizens, the Government has established the following law, of which we make a short extract:—

Sec. 1. The slaughtering of horses or asses, for the purpose of the sale of the flesh of these animals can only be performed in special slaughtering-houses, specially licensed for the same.

Sec 2. The sale of the flesh of these animals can only be carried on at such places as previously have been indicated to the police authorities.

Every place of this kind must be provided with a large sign, on which may be read, in large and legible letters, the words, "Sale of horse flesh." Other meats cannot be sold at such places, only the flesh of horses and asses.

Sec. 3. No horse and no ass can be slaughtered, till the animal has been re-examined by a veterinary surgeon permitted to make such legal examination.

The animal has to be slaughtered on the day it has been examined. Its flesh cannot be exposed for sale till the veterinary surgeon, after having examined the split head and the lungs of the animal, has entered his permission into the butcher-book.

Sec. 4. Every horse butcher has to keep a butcher-book, which must be approved by the police authorities and be arranged as follows:—

1. Current number.
2. Description of the animal, its sex, age, size, color, weight and special remarks.
3. Day of its purchase.
4. Name of seller and remark on his standing.
5. Veterinary surgeon's certificate of the health of the animal.
6. Day of slaughtering.
7. Permission of the veterinary surgeon, for the sale of the meat.

The rubrics 5, 6, and 7, are filled out by the veterinary surgeon.

Sec. 5. It is forbidden to buy such animals from unknown persons not legally authorized to sell the animal. How the person selling the animal has proven his identity and his standing, has to be remarked under 4.

Sec. 6. Before such flesh can be imported the special police permit must be asked for and obtained.

If horse butchers buy such meat of others in the same trade, the police authority has to enter in the butcher-book the weight, and the number of the other book, and to add the permit given, in writing.

Sec. 7. Infringements are punishable by a fine of $20, or imprisonment for four weeks.

It would be well, for the health of our citizens, if our government would become equally parental in the sale of cattle, etc.

PNEUMONIA AN INFECTIOUS DISEASE.

That acute, lobar, croupous pneumonia is considered by some an infectious fever, with evident tendency to the lungs, or as now better expressed, a zymotic disease, caused by the inhalation of bacilli, which accumulate mostly in a lower lobe of one lung, we have often had occasion to note. The proofs of this statement accumulate daily.

Dr. Köhnhorn found that the disease had become endemic in one of the barracks at Wisel. Occasionally it broke out as a local epidemic. The regiment stationed there had suffered frequently from the disease. Not a year passed without many falling a victim to pneumonia. The regiment was then placed in other quarters, and no further case happened in this regiment. The barracks were torn down, the soil disinfected most thoroughly, as also all the building material. Since the regiment has been camping in these rebuilt barracks not a solitary case of pneumonia has made its appearance.

Notes and Comments.

Phlegmasia Alba Dolens.

To the St. Louis *Courier of Medicine*, Dr. P. V. Schenck contributes a lengthy article on this subject. After reviewing the various opinions that have at different times been advocated concerning its etiology, and leaving the matter in as much doubt as ever, he comes down to treatment, in which we find the following practical suggestion: "There is no doubt that bandages aid the absorption of the effusion, and diminish the size of the limb, and the advisability of this treatment is no longer questioned. The only point is when to use it, and how to apply the pressure, and what material to use. The fresh skin of animals was once used, and it was supposed to possess a certain advantage outside of the mere pressure. Next muslin was tried, then flannels, then chamois skins were applied, then silk in the shape of long elastic stockings; but my experience has been so favorable in the use of Martin's rubber bandages that I think it worth while to call the attention of the profession to their application. The use of these bandages has become almost universal; there is no need of describing their mode of application, every surgeon applies them, the general practitioner employs them, and the obstetrician and gynecologist are now trying them, as a utero-abdominal supporter.

The Radical Cure of Varicocele.

In the *Deutsche Medic. Zeitung*, III, 16, '82, we find a description of a method of operation which has proven very successful for the cure of varicocele in the hands of Dr. Reg. Harrison, of Liverpool. The operation recommends itself by the fact that recurrences after this method have not been observed.

The procedure is as follows: After the cord has been laid bare by a vertical incision of about one inch in length, those varicose veins which appear especially prominent are, each by itself, ligated with a catgut ligature (usually 3 to 4). The smaller veins, which generally are met with in different numbers and in form of plexus or bundles, especially in the neighborhood of the epididymis, are destroyed with a few light touches of the thermo-cautery, while the vas deferens is held between thumb and forefinger of the left hand and carefully protected against any injury. This permanent destruction of the small veins is essential, as in this way alone any recurrence can be prevented. During and after the operation perfect antiseptic treatment, and no suture. The cicatrix formed by granulation looks well and is contractile.

The very old method of removing a piece of the scrotum, as practiced by Dr. Henry in New York, and Dr. Levis in Philadelphia, is not thought well of by Dr. Harrison.

Ligature of the Innominate Artery.

Mr. Thompson's patient, an account of whom has already been given (see Reporter, August 5th, 1882), died July 20th, the forty-second day after ligature of the innominate artery. There was no recurrence of bleeding after the thirty-ninth day. The sinus was found to terminate in an ulcer, which involved the anterior wall of the junction of the innominate, carotid, and subclavian arteries. The innominate and carotid were filled with clot; the subclavian contained a clot occluding it to the extent of half an inch. The position of the ulcer was on the distal side of the ligature, the constricted portion of the innominate not being involved. The hemorrhage had apparently taken place from the innominate, as there was a recent blood-stain on the cardiac side of the clot. None of the vessels were pervious to water forced in with a syringe. The aorta was atheromatous. Consolidation was proceeding satisfactorily in the tumor. Excluding the successful case of Dr. Smith, of New Orleans, this is the second longest survival on record; Graefe's case having reached the sixty-seventh day, and Cooper's the thirty-fourth.

Isolation in Contagious Diseases.

At a recent meeting of the Académie de Médecine, M. Hillairet read a report prepared in answer to a question asked by the Minister of Public Instruction, regarding the length of time a pupil affected with any of the contagious diseases should remain separated from the other pupils. M. Hillairet's report may be summed up in the following propositions: 1st. Pupils suffering from varicella, smallpox, measles, mumps or diphtheria should be completely isolated and hold absolutely no communication with the other members of the school. 2d. Isolation should continue forty days for smallpox, measles, scarlatina and diphtheria; twenty-five days for varicella and mumps; the patient should have repeated baths before being allowed to join his comrades. 3d. The clothes worn by the patient at the time he fell sick should be submitted to a heat of 90° C., and then to repeated fumigations

of sulphur. 4th. The bed-clothes, curtains, carpets, furniture, and even the walls of the room occupied, should be carefully disinfected, washed and aired. 5th. If the pupil is taken sick at home he should not be allowed to return to school without the certificate of a physician attesting that all these precautions have been faithfully carried out.

Ether.

In the *Lancet*, Dr. H. Bendelack Hewetson discusses the relative value of ether when prepared with "rectified" or "methylated" spirits of wine. The author states that there is a great difference between them. That prepared with rectified spirits has been found by those who have used it less safe and less desirable, producing more sickness and laryngeal spasm in certain cases in which there is a tendency to such complications. Of the use and applicability of the methylated ether—as the safest anæsthetic known, when carefully administered by means of Clover's inhaler—he can speak strongly, as the result of daily observation. It is a very ordinary circumstance to occupy eighty seconds in producing complete anæsthesia, without a struggle or a cough, and it is by no means extraordinary for a patient to be "fully under" *within* the minute. In the case of short operations upon the eyes, and the like, it is hardly ever necessary to reapply the inhaler after it has been once removed for the operator to commence, the patient remaining sufficiently anæsthetic for an operation such as mentioned to be completed without hurry. Anæsthesia can be prolonged with equal safety even so far as to keep a patient in labor completely under its influence for upward of *four hours*, the longest time which has happened in my experience. Methylated ether is, I consider, from this point of view, the safest and cheapest anæsthetic at present in use.

Retroflexions of the Uterus and Painful Menstruation.

At a recent meeting of the Obstetrical Society of Dublin (*British Med. Jour.*), Dr. Hermann read a paper on the above subject. He discussed at some length the influence of retroflexion in producing difficult menstruation, and offered the following conclusions:—

That while dysmenorrhœa accompanying retroflexion is often, it may be generally, dependent upon other concomitant conditions, yet there are cases in which it is simply the result of the displacement; and that in such the dysmenorrhœa is probably entirely due, not to the flexion, but to the veins of the broad ligaments being compressed against the utero-sacral ligaments.

He said it was impossible to avoid reasoning from pain; and he thought that, by taking a large number of cases, errors due to the incorrect statements of a few individual patients became neutralized. He did not think that the cases in which the utero-sacral ligaments caused congestion of the uterus were more than a small minority.

Permanganate of Potash, in Gonorrhœa.

Prof. Zeissl, of Vienna, recalling the accidents which may result through the employment of caustic injections in the treatment of gonorrhœa, stated that he had observed in the Vienna Hospital a number of cases of stricture, which he considered due to the employment of too concentrated a solution of permanganate of potash. This method is, it may be said, at the present time, à la mode with the physicians of Vienna.

The good effects obtained from it in the treatment of gonorrhœa cannot be denied, but Prof. Zeissl affirms that the employment of a weak solution is without caustic effect, and yet possesses sufficient astringency to obtain the desired effect. This he has proven in many cases with the following solution:—

℞. Potass. permanganat., gr. $\frac{1}{6}$
Aquæ, ℥ ij. M.

The Elastic Ligature for Opening Sinuses.

In the *Medical Times and Gazette*, Dr. Henry A. Lediard recommends the use of a fine rubber ligature in opening up sinuses about the posterior part of the mouth. He relates the case of a patient with several sinuses in and about the soft palate on the right side, and in the neighborhood of the tonsil, resulting from repeated abscesses of long duration. A scanty purulent discharge was always present, causing a disagreeable taste in the mouth in the morning. A considerable amount of cicatricial tissue was present near the right tonsil and about the soft palate. A probe searching behind the velum found its way into a sinus, and the point of it projected the tissue above the last molar tooth. He cut down upon the probe point with a view to establish complete drainage through the incision, which, although very small, caused a lingering hemorrhage, which was not checked without trouble. In order to find the course of the pus, which still appeared, he passed some fine elastic, tied to a thread upon

an aneurism needle, through the track above mentioned, and tied it; in forty eight hours the tissues were cut through, and a sinus laid open. No hemorrhage and only bearable pain resulted. The effect was beneficial, but other sinuses appeared still, behind, in parts considerably altered by the old inflammatory action. He accordingly repeated the process, passing the ligature partly through a blind sinus, and bringing it out through healthy parts; and this was done altogether three times, with the result of complete cure.

Perforation of a Gastric Ulcer into the Left Ventricle of the Heart.

This peculiar condition was detected in the case of a laboring woman, aged 55, who died with the symptoms of a perforating ulcer of the stomach. During life the remarkably irregular action of the heart had been noted, but found its explanation only after death, in the lesion of the muscle of the heart. There existed, besides, a left-sided pleuritis, caused by the ulcer. This pleuritis had produced adhesion of the diaphragmatic pleura to the pericardium. In consequence of this the base of the ulcer had been brought in direct contact with the pericardium, and so caused a perforating ulcer of the left ventricle of the heart. The seat of the ulcer in the stomach was distant five ctm. from the cardia, and situated in the lesser curvature.

Accidental Removal of Uterus—Recovery.

At a recent meeting of the Obstetrical Society of London (*Amer. Jour. of Obstet.*) Mr. Hopkins Walters exhibited a uterus with one ovary and Fallopian tube, and a piece of omentum that had been torn away by a midwife in the attempt to remove an adherent placenta. The patient made an excellent recovery.

Hemorrhagic Polypus.

At a recent meeting of the Obstetrical Society of Dublin, Dr. Henry showed a tumor (*British Med. Jour.*) which had been expelled from the uterus of a woman on the previous day. In March last she menstruated normally, but her period did not appear in April. In May, at the menstrual period, she felt something moist come away, and then a gush of blood followed. In June she expelled a three months' fœtus, and on June 30th the mass now shown came away, it having been previously felt in the uterus. The tumor consisted apparently of blood-clot, to which remained attached the membranes, placenta, and cord of the fœtus, expelled eight days before. It was thought the case was one of what had been called "hemorrhagic polypus."

Meniere's Disease.

The following case from the *British Medical Journal* well illustrates the necessity of caution on the part of the public in forming opinions on matters relating to medicine: On the 21st of last October a court of inquiry was held to inquire into a charge of drunkenness preferred against a sub-constable. He had been seen to stagger and reel while on duty. He was taken to the barracks, where, in a short time, the transient attack of giddiness having passed away, he seemed, as he really was, perfectly sober. He was seen two hours afterwards by Dr. John Ringwood, when he exhibited well marked symptoms of Menière's disease; noise and hissing in his left ear, numbness behind the ears and down the left arm, depression, occasional vomiting, giddiness, objects going to the left side, the drum of the ear inflamed, and the left Eustachian tube plugged. Improvement followed inflation with the Eustachian catheter.

Butternut as a Preventive Remedy in Abortion.

Dr. Bell Morrelton reports (*France Médicale*) several cases in which the extract of butternut (juglans cinerea) seemed really efficacious in preventing abortion.

He employs the following mixture:—

℞.	Ext. hyoscyam.,	ʒj
	Ext. juglans cinerea,	ʒj
	Ol. sassafras,	℥ss
	Sodæ bicarb.,	ʒss
	Syr. simplicis,	℥vj. M.

A teaspoonful of this mixture may be administered three times daily during the entire period of pregnancy, after the threatened abortion.

The same physician has also employed this remedy in scrofulous affections and as an injection in leucorrhœa.

Deaths of Children from Syphilis.

The *British Medical Journal* notes that during the past eight years as many as seventy eight children have died in Sunderland, from syphilis. This is according to statistics, but it points out the fact that this can hardly represent the true mortality, since medical men, in giving certificates of death, could not, in many cases, state syphilis as a cause, lest by so doing they would cause much domestic misery.

Œsophagotomy.

The *Lancet* notes that the œsophagus has been recently opened in London, by Dr. Stephen Mackenzie, for cancer, in the case of a man sixty years of age. The walls of the œsophagus were so cancerous that it was difficult to recognize it, and they were so friable that the attempt to secure it to the skin was abandoned and a large elastic catheter was introduced and tied in. This operation is of value in so far as it tends to dispel the hitherto generally accepted belief as to the danger and difficulty of the operation when undertaken for stricture. A full report of the case will be given when all the details are complete.

Cause of Red Sweat.

That blue sweat was due to micro-organisms, and that the latter are found even in yellow sweat, has long been known. Babesin reports to the *Ctrlb. f. d. Med. Wiss.*, that he has been able to detect bacteriæ in red sweat, and especially in the hairs of the armpit of such a case. He considers these bacteriæ to belong to the same class as all chromogenic bacteriæ, being very much like the bacterium prodigiosum. They are easily destroyed by disinfecting solutions of proper strength.

Treatment of Styes.

As a means of "backing" a stye, Dr. J. P. McGee, of Tennessee, states that the practitioner can use to advantage the following treatment:—

℞. Fl. ext. belladonnæ, gtt. iij
Aquæ pluv., ℥ ij. M.
Sig.—A teaspoonful every hour.

At the same time he may give calcium sulphide, $\frac{1}{8}$ or $\frac{1}{10}$ gr. every hour, for five or six doses, then every three; although the belladonna is often sufficient alone. Remember, this is sufficient only in the very early stage of the affection—within the first six or twelve hours. He will find it "back" at least three of the five.

Suture of Tendon.

Dr. Yeats recently presented a case to the Manchester Medical Society (*British Medical Journal*) where he had, six weeks after an accident, united with four catgut sutures the divided ends of the tendon of the extensor communis digitorum of the middle finger, at the metacarpophalangeal joint. The skin wound was united by silver sutures. The operation was done antiseptically. The wound healed in four days; and three weeks afterward the patient had perfect control over his fingers, flexion and extension being perfect. At the end of five months the fingers were as strong and useful as before the operation.

Pasteur's Inoculation Questioned.

The *Medical Times and Gazette*, quoting from the *Revue Med.*, says: M. Duclaux, Professor at the Agronomic Institute, and charged with the delivery of a course on Chemical Biology, at the Sorbonne, has devoted a chapter of his work, "Ferments et Maladies," to the consideration of M. Pasteur's inoculations. We know that M. Pasteur takes a virus, cultivates it under determinate conditions which are still kept secret, and professes to transform it into a "vaccine" virus, which, when inoculated, preserves an animal from a disease caused by this same virus when not attenuated. We are of opinion that he does nothing else than the practitioners of former times did when they inoculated smallpox, and which those of our contemporaries have so unfortunately done in inoculating syphilis, with the object of preserving from diseases that can only be taken once. Three circumstances may occur—1. The animal inoculated is not favorably disposed for the infection, the virus does not take, and there is no result; 2. The virus takes and a slight form of the disease is produced, which preserves from an ulterior attack; 3. The virus communicates a dangerous form of the disease, and the animal dies. This last case occurs pretty often after the vaccination by the Pasteurian procedure, and perhaps not a week passes in which carcases are not received at Alfort that have had no other cause of death. There is no analogy whatever between the Jennerian vaccine virus employed for prevention against the smallpox and the *virus-vaccin* used by M. Pasteur. Never has vaccination given rise to the production of variola; and variola and vaccinia have been observed in a state of simultaneous evolution in the same individual. Never has vaccination caused death, except when the virus has been mixed with virulent pus; while this *virus-vaccin* has already killed a number of animals. What number? This should be stated in a matter of such importance.

Such accusations should have strong authority to substantiate them, else they had better be left unmade.

—Professor Kundral has been appointed successor of the celebrated Heschl at the University in Vienna.

Correspondence.

Veratrum Viride in Puerperal Convulsions.

Ed. Med. and Surg. Reporter:—

On Friday, April 30, 1880, I was called to see a colored woman, aged about 19 years. Found her in convulsions, which were quieted in a few moments by the inhalation of ether, and by 5 minims of tinct. verat. viride (Norwood's), subcutaneously. After she became quiet the husband informed me that she had been suffering with great pain for several hours, which gradually became worse; about one and a half hours before I saw her she had her first spasm; her fifth was the first I saw the patient in. It was the most severe.

This patient was well advanced in labor. I found the os dilated well; head in the first natural position (acccording to Miller, left occipito acetabular). Labor progressed very slowly, uterine contractions being feeble, and after waiting half an hour found the womb still inert. I decided to excite the action of that organ. I injected, hypodermically, 10 minims of ergotine and 5 minims of tinct. verat. viride combined. I used the latter for fear of a return of the spasm, which did occur as soon as the uterus became active. During this spasm the membranes ruptured spontaneously, a ten-pound male child was born, and twenty minutes after placenta, etc., were taken away.

I waited the usual "hour;" finding no recurrence of convulsions, nor any flooding, I left her doing well. What the convulsions were due to, I think, was her condition; she having suffered several months from malarial fevers, which had nearly exhausted her strength, she became anæmic.

When I first saw her she was suffering great pain from œdema of the lower extremities. Her face was swollen to almost disfiguration. Strange to say, the patient's urine showed but a small quantity of albumen on the proper test for same.

By means of the "tonic and suppurative treatment" my patient made a good but slow recovery. The reason I report this case is, that I have had the opportunity of treating some cases before, and have had several since this one, with equal success (except one), with verat. viride.

I intend to use this remedy whenever a case presents itself, and hope those of the *regular* profession who have not tried it, under the circumstances above mentioned, will give it a fair test.

Do not wait to give the remedy by the mouth, but give it hypodermically.

Natchitoches, La. W. B. Powell, M.D.

News and Miscellany.

British Medical Association—Meetings of Sections.

SECTION OF MEDICINE.

The address in the Section of Medicine was delivered by Dr. T. Clifford Allbutt, who chose the subject, "*Modern Freedom of Thought and its Influence on the Progress of Medicine.*" He said, what is that spirit, which, in this century, has expanded and transfigured our art? It is not the new power of unity alone, that strange, new function which is bred in gatherings of men, a thing higher and other than the mere addition of individual faculties; this union the press and the railways have made possible; but there is that something more, some masterful expansion which has widened the life and nerved the arm of modern science. This comes, gentlemen, of the gift, without which all other gifts are but as apples of the Dead Sea, the gift of freedom. The withes whereby, for a thousand years, men were bound in body and soul, are broken; the dissolution of that tyranny which stalked, halted and baited the man who dared to think for himself, is fulfilled in our own time, and no longer is it declared to men, "Thus, and thus only, shalt thou think of God and Nature." Man has won three victories; he has vanquished the terrors of the old world, brought forth food, warmth and light upon the face of it, and thus ceased to be Caliban, the earth slave. Then man became a nation; nations strove for the mastery and political freedom; his second victory was won. Lastly, with the earth his servant and his civil rights secured, the final and crowning work remained, to win the freedom of his mind.

As men more and more deeply studied the life around them, they found themselves led into new realms of experience, and to conceptions far wider than they had dreamed of. At last the old and binding idea of force and matter as dual, was seen to be factitious, and most mischievous in this, that it divided the faculty of thought into two worlds—into the several worlds of philosophy and of natural history. The former was to be regarded as the higher and chosen sphere of noble contemplation, though, uncoupled with nature, it brought forth nothing; and the latter had the sterility of neglect. We now see once more that this dualism is a phantom, and that force and matter are but one subject under two names. Natural processes are no longer to be regarded as the work of inert atoms, whipped by tangential agents; nature herself is no longer to be studied as a mere framework, pumped by a vital principle, which is itself the nobler object of pursuit, but which submits not to a like study, eluding inquiry or subject to a special and alien kind of illumination.

But when we have learned that matter and force are one, that atoms are force-dust, and that we are in the presence of infinity in either sense, inward or outward, then we know that the soul may be kindled and the mind fed by depth of penetration as richly as by the loftiest aspirations. As Browning tells us, in Paracelsus, "to know rather consists in opening out a way whence the imprisoned splendor may escape, than in effecting entry for a light supposed to be without." The very terms materialism and idealism thus cease to signify an opposition, and fall meaningless to the ground, and the microscope is seen to be as true a source of inspiration as the *Paradise Lost.* No longer, then, thrust back from scientific progress by the reverence of antiquity and the authority of those of high repute in philosophy, which have held generations of men as by an enchantment, we have now, in the last fifty years, seized upon the real strong-

hold of truth, and have added to the riches of the knowledge both of universe and mind, in a measure unexampled in the former history of man. We have won that freedom for our great workers and thinkers, which gives them power to speak and spread forth their doctrines openly.

Till these studies are more complete, and as yet they have scarcely begun, we cannot hope for a system of medicine, but must content ourselves with a mere *corpus prescriptionum*. Toward this higher phase of our own art let us strive. Until we can eliminate the chief morbid factors which affect us from without we cannot understand our failures from within. In his treatise on "Airs, Waters and Places," Hippocrates laid the foundations of the study of the external factors of life; it has been left to our own day, and to such men as Pasteur, Lister and others, to advance this research from the study of the inorganic factors to that of the organic. Another great and curious department of knowledge has been opened out to us in the embryological interpretations of the phenomena of disease; these being traced either in arrested development, as in many defects and deformities of body and mind, or in retrogression, such as leucocythemia. The comparison of embryonic periods in the same and in different animals may be the master key even to the diatheses themselves, as may be suggested, for instance, in the chief functional disorder of lithiasis, wherein the formation of urates in place of urea is the resumption of a state normal to inferior types. The strumous diathesis, again, is, it would seem, a permanent arrest of development at a stage short of the highest, and may indeed be, and commonly is, artificially attained by exposure to conditions such as deprivation of light, etc., acting in arrest of completion of growth, as we know that they do in the case of the lower forms of life. The later work of our histologists is full of suggestions of this kind, drawn from the study of heterogeneous growths. Many great lines of thought and observation are thus convergent upon the study of medicine, and are enlarging the foundations of the science, upon which alone the successful art can be reared. What we have then to-day to proclaim is, that during the last half century we have ceased to build castles in the air, have turned more frankly and loyally to nature, and have sought our inspiration and found our reward in the study of phenomena which our forefathers despised as gross and immaterial. As did anatomy, two hundred years ago, so in our own time, has medicine conquered her independence; for this other men have labored, and we are entering into their labors. And although our ways be still dark and slippery, I trust that those who shall be gathered together in our hundredth *Comitia Tributa* may rejoice in a yet more glorious light, and may think gratefully of us of to-day, for in the words of a modern poet—

> "The first still follows one that goes before;
> The last still hears a toiling foot behind."

SECTION OF SURGERY.

In this section the address was delivered by Augustin Prichard, F.R.C.S. After some preliminary remarks, he touched upon the difficulty which existed but a few years ago, comparatively, in procuring an adequate supply of material for dissection. It was but a few years after the passage of the Anatomy Act, an uncle of mine, a very promising young man, died of disease of the chest, the effects of cold caught by being locked up with a fellow student half the night, in a damp cell, in his wet clothes, having been caught while out on an expedition such as I refer to. These events were long ago, it is true; but we can hardly admire sufficiently the zeal, born of necessity, which took these young fellows out after the work and amusements of the day was over, at the smallest hours of the morning, dressed as laborers, and armed with lantern, shovel and pickaxe, to some dark churchyard, then dig open the newly-filled grave, get out the body, and drive it home in their gig before the town was astir. A late colleague of mine, who taught anatomy in Bristol, under these difficulties, in what some of you may consider prehistoric times, has, before now, shown me a heavy bunch of huge keys, all ticketed, which were duplicates that unlocked all the churchyards of Bristol and its neighborhood. Some few of the stories connected with these events have been published from time to time, in Sir Astley Cooper's life, for example; but there are members of our profession still living who shared in these dangers and difficulties, and it would be well worth while if some one would collect some authentic account of these doings, before the whole generation passes away, and before they come to be considered an incredible and impossible part of our professional history; and to make this suggestion is one of my reasons for touching on the subject.

After deprecating the undeserved and unwise neglect of venesection in appropriate cases, which obtains to day, the speaker touched upon counter-irritation, which he considers a most important means of treating chronic disorders.

We are now taught to look with suspicion, if not with dread, on a drop of pus; our predecessors called it laudable; and in my time numerous and ingenious were the devices to produce a suppurating surface. I have no wish to defend the treatment, such as I saw formerly, when Dieffenbach and Jüngken, at Berlin, and Velpeau and Roux, at Paris, after an amputation, would fill the stump between the flaps of skin with dry charpie, before bringing them together with bandages, to ensure a good suppurating surface. The mortality after these amputations was a sufficient warning against the plan; but for chronic joint disease, for chronic eye disease of various forms, especially the chronic inflammation of the cornea, for chronic inflammation of the middle ear, and I believe, for a very much larger number of chronic internal maladies in the domain of the physician, a seton or issue, or some other discreet mode of counter-irritation, is of the greatest service, and not nearly often enough used.

Some good operations have been dropped into disuse on account of fashion or some other equally irrational cause. Some such inadequate cause no doubt first started the growth of the great medical imposture, homœopathy, which has attained such a development among us; and although it has invaded the territory of the phy-

sician much more than ours, I nevertheless think that it has had the effect, in some degree, of discouraging, or diverting into the wrong channel, the search for pathological truth.

Before the time of anæsthetics, operations were performed with great rapidity. I think that I have noticed, as far as my opportunities go, a tendency to greater deliberation and slowness of procedure in operating; and this I hold to be a mistake, for I am convinced that the shorter the time that the patient is under the influence of an anæsthetic, and in the hands of the operator, the better.

There is an operation which, after resuscitation, is in great danger of being buried again, and I should like to say a word against its reinterment. I allude to median lithotomy. There will always be difficult cases of stone in the bladder, which lithotrity, with all its improvements, will not be able to touch, and which must be cut. The advocates of the median section, and I confess myself to be a warm one, contend for it that, while it is equally efficacious, it is, in the adult, a less dangerous proceeding than the lateral operation. I have not such frequent opportunities, as I had formerly, as one of the acting surgeons of the Bristol Royal Infirmary, of performing lithotomy; but I have done no other kind of cutting operation for stone for many years, and in any future case should certainly have recourse to it again. In the young boy, the operation is more difficult; and although the usual lateral section is very little fatal in young subjects, I think that the median has two definite advantages. There is less risk of hemorrhage from a cut in the middle line, wherever it is, and the little patient is able to hold his urine sometimes from the actual date of the operation, or the next day, but always much sooner than when the neck of the bladder has been divided laterally. In many cases they have been known to get up and run about the room in two days. In the case of the adult, the wound would not be so deep, there is little or no fear of bleeding, and the power of retaining the water in the bladder is not so completely lost. I have removed stones weighing upward of three ounces, by this method, without any difficulty.

Surgery claims for herself her full share of the wonderful inventions and improvements of this energetic age; and no one may foresee what wonders the next twenty years may bring forth. She is going on in nearly parallel lines with her sister, Medicine, having the same terminus to reach, viz., the relief of human suffering; and at the many points where the lines closely approximate we get the benefit of the recent therapeutical discoveries which she has made, while we, on the other hand, more than repay the debt by the help we are frequently called upon to give.

SECTION OF ANATOMY AND PHYSIOLOGY.

Dr. George M. Humphrey delivered the address in this Section. Touching upon the divergence of physiology and anatomy from one another, he said that it was perfectly natural. As the several members of the great family of science grow older they grow larger, fall away from one another, occupy independent ground and independent laborers, and form centres from which new individualities will in time bud off. In the present instance the separation is, in the main, due, and is the natural and necessary result of, the development as well as growth of the younger of the two sisters which, during the last half century, has been not only unceasingly but in geometrical ratio expanding. It deals with minute structure and the associated delicate processes, leaving to anatomy the investigation of the coarser structures of the body, those which can be carried out with the naked eye. Anatomy is so nearly complete as a science that it is but little progressive. The books on anatomy contain little or no allusion to the practical import of the several structures and their disposition, and the methods of description have usually no reference to this point. All the features are placed too much on the same level, without light and shade, and the whole landscape proves to be proportionately dull and uninviting. This is alse a result--I fear an inevitable result--of that increasing subdivision of labor which causes the investigation and teaching of anatomy to devolve more and more upon the pure anatomist. Moreover, the anatomist does not seem sufficiently alive to the value of that kind of physiological knowledge which is the proper associate of anatomy and which appertains to it in the same way as the study of process appertains to the study of minute structure. Too often the bare naked facts are marshaled in solemn dullness, one after another, and are crammed down the reluctant throat of the student, without spice or flavor of any kind, not to be digested, but to be gulped again, much as they went down, under the examination squeeze. I regard anatomy not only as the veritable basis of medical knowledge, but as the veritable basis also of medical education, and I therefore wish it understood that I by no means deprecate the pure, simple study of anatomy, and it is no small satisfaction to me to have the opportunity of seeing the senior wrangler and the senior classic humbly and cheerfully bending in the dissecting room and applying the earnestness and ability which has gained them their high positions to the elucidation and appreciation of the disclosures which their own forceps and scalpel can make.

Thus, as I grow older, I grow stronger in my respect for anatomy *per se;* but I grow stronger still in my estimation of its capabilities to excite interest, to nurture inquiry, and to strengthen the mental faculties by virtue of the practical and physiological expositions which are its legitimate accompaniments. I feel that its educational as well as its practical value would be greatly increased, if the relations of form and structure to disease and accident and treatment were more fully pointed out. A careful and accurate description of the form of the tibia, for instance, may be and is good in itself; but an account which associated that form with the liabilities to accident and disease, with the various distinctive peculiarities of the human form and gait, with the laws of growth and development, would be far more improving and impressive, because more instructive and suggestive. A student looks at the *plantaris* muscle in the leg. He wonders what need there is for it, and how it comes to be there. He sees that any slight as-

sistance it may render to the great calf muscle is scarcely a sufficient pretext for its existence in a separate form, and he finds relief and pleasure in learning that this little muscle is an *attaché* to the short flexor of the toes; that its severance has been caused by that projection of the heel-bone which is one of the attributes of the erect posture; and that, when it is continuous with the foot-muscle, as is the case in most of the lower animals, it is clearly seen to be the homologue of the *flexor digitorum manûs*. Possibly, he may still indulge in the luxury of speculating as to the law of evolution, by virtue of which it has maintained its individuality through so many ages of comparative uselessness. He looks with vastly increased interest upon the construction of the great toe, when he learns by what slight modification from the lower animal form that solidarity has been given to the human foot, upon which, more than upon any other single specialty in his anatomy, the preëminence of man is due; and he views with respect the flexor and the middle extensor of the thumb, upon finding that the complete segmentation or separation of these muscles from their surroundings is to assist in correlating the free mobility of the human pollex with the fixity of the human hallux. He is agreeably surprised to find that the dry bones in the open valley of the class room are made to live and stand upon their feet, an exceeding great army of instruction and interest, when breathed upon by the teacher, and clothed by him with the warm flesh and blood of development, morphology, mechanical purpose, and practical bearing.

I have said enough to show my hope and my confidence that the anatomy of the coarser structures, with its attendant physiology, will not be allowed to pass into the category of subjects dead and barren as regards scientific character; but that it will be more and more cultivated, not merely for its practical value, but as a repertorium of scientific interest.

With regard to the special subject of physiology, which has relation to minute structure, and more particularly to composition and processes—that is, the *changes*, chemical and physical—of structure, we may be sure that it will never cease to command interest and to engross a large share of attention. It will always be able well to take care of itself. It is essentially and rapidly progressive, and it is illimitable. Its investigations lead in those directions in which there must ever be a near border-land of the seemingly mysterious and inscrutable, to fascinate and tempt the inquirer on. It dives into the deepest recesses of nature's works. It brings to its aid, and gives the greatest range to, chemistry, physics, and mechanics, and advances with them, its progress being checked mainly by their imperfections. It profits by the newest refinements of optical and other instrumental apparatus. Its searchings cannot be confined to dead matter. The very essence of the science demands that the processes, "living as they rise," should be submitted to its scrutiny. It is quite certain that this must be done, and will be done, largely, whether in England or abroad, whether in this generation or the next, whether under Parliamentary control or under trust in the good feeling and conscience of educated men.

The greatest accession to knowledge in medical science which has been made during the era of this Association—one, indeed, of the greatest ever made—is that included under the term "cell-development," which was worked out, in the first instance, by Schleiden and Schwann. This has caused a re-casting of all our ideas of nutrition, including development and growth; and has, at the same time, given an entirely new ground to the science of pathology; for it has shown that the agents which are the media of nutrition are the media also of those modifications of nutrition which we call disease. It has taught us that a malignant cancer growth is probably the result of a perversion of, perhaps, intrinsically only a slight departure from, the ordinary and normal processes of cell growth in the natural tissues; and the suggestion brings with it a ray of hope, that these deviations may one day be checked or prevented, and that this most terrible scourge of humanity may be amenable to treatment. Associated with this great theory are the investigations respecting the movements, the migration, and the absorbing properties of leucocytes, which, as well as the investigations respecting the influence of the medulla oblongata and other ganglionic centres, great and small, upon the action of the heart and blood vessels, and the investigations respecting the formation of sugar and albumen and their modifications, have a very direct bearing upon various pathological processes, and upon some of the most common and important diseases, and must lead to the better treatment as well as the clearer knowledge of those diseases.

The Dangers of the Dairy.

The *Medical Times and Gazette* reports the following instructive case: In the course of a house-to-house inspection, by the inspector of nuisances, he found a family, four members of which had been ill from smallpox during the previous five weeks. No medical man had attended the first case, nor had anything been done to prevent the spread of the disease, either in the house or out of it. The whole family was in a filthy and neglected condition, and the head of it was a man, who, during the five weeks, had been in constant work, in the employment of a dairyman, his duties being the delivery of milk. The existence of the disease in his family had been kept from the knowledge of his employer, who, however, dismissed him from his service on learning from the Board the circumstances of the case.

Professor Von Langenbeck's Successor.

The *Medical Times and Gazette* says that the *Berliner Klinische Wochenschrift* makes the following observations upon the difficulties which lately arose in supplying a successor to Langenbeck: "Our readers are aware that not only Billroth, of Vienna, but also Volkmann, of Halle, declined complying with the call to Berlin. We cannot but, in the interests of our University and city (a large circle in which has manifested great

interest in this nomination), express the liveliest regret at the refusal of two such men, whose names, especially that of the former, must necessarily present themselves when the first German surgeon is sought to be obtained for the chief city of the German Empire. It would, however, be entirely untrue to assign these refusals to any other cause than the personal relations which both clinical professors have established with their respective Universities. And Volkmann's refusal is a strong proof how little reality there is in the fear created phantom that a powerful centralization is to be dreaded. If a town and University like Halle can maintain a rivalry with Berlin, and fetter the wishes of a power of the first rank, this shows how far we, to our great joy, are removed from the condition of things which prevails, for example, in France, where such an occurrence would be an impossibility."

A New Sanitary Association.

Under the presidency of Dr. Cameron, a meeting has been held in Liverpool, to establish an organization, to be called the "Northern Sanitary Association." The object is to provide the best practical advice on sanitary matters at a moderate cost, and to advance sanitary knowledge. A resolution was adopted in favor of such an association, which was influentially supported, the Earl of Derby being the president.

Factory Legislation in France.

Fresh powers for enforcing an old Act of 1848, regulating the duration of the day's work in factories, have been obtained from the Chamber of Deputies by the French government. This law, which fixed the maximum length of a day's work at twelve hours, had almost fallen into desuetude. The inspectors under the Act will be largely reinforced, and the condition of working children is to receive special attention.

Items.

—Prof. Zuckerhand'l has been appointed Professor of Descriptive Anatomy in Gratz.

—The yellow fever prevails as an epidemic in Pensacola, and there is much distress there.

—Diphtheria is reported in a malignant form in some localities in western Pennsylvania and West Virginia.

—In Berlin, during last year, 1809 persons lost their lives by accidents, and 411 persons committed suicide.

—Prof. Fritsch has been elected as Professor of Gynæcology in Breslau. He is the successor of Spiegelberg.

—The position of Professor of Morbid Anatomy in Paris has not been given to Hayem; Cornil has been appointed.

—The Norristown Insane Asylum, in this State, is attacked in the newspapers, for alleged brutal treatment of patients.

—Prof. Joseph Decaisne, the celebrated botanist, died in Paris a few weeks ago, at the age of seventy-six years. He was a pupil of Jussien.

—In Vienna the city government has given, in honor of Skoda, to a recently opened street near the "Allg. Krankenhaus," the name of *Skoda-Gasse.*

—The celebrated naturalist, especially known for his studies in zoölogy and geology, Desor, Professor in Neuenburg, died recently, in his 72d year.

—As candidates for the chair which, at the University of Gratz has become empty by the call of Kundral to Vienna, Prof. Eppinger (Prague), and docent Dr. Weichælbaum (Vienna), have been named.

—Professor Klebs, who gave, by his researches into the cause of typhoid fever, some reputation to the University of Prague, has accepted a call from Zürich, where he is now Professor of Morbid Anatomy and Pathology at the University.

—Six more of the celebrated anatomical plates of Mesal, which, after a drawing of Tizian, were cut in wood by Kalkar, have been detected by an accident. They had been bought from a second-hand dealer, and possess an enormous value.

—On August 31st, the Union Medical Association, composed of physicians of Pennsylvania and Maryland, held its fifth annual meeting at Wildcat, Lancaster county. An address was delivered by the President, Dr. W. Stump Forwood, and an enjoyable day passed.

OBITUARY NOTICE.

DR. EDMUND L. B. WALES,

who died at his residence at Tuckahoe, N. J., on August 18th, was a gentleman well known throughout the State of New Jersey, as well as in this city. During his extended professional life he acquired considerable reputation, and through successful financial operations accumulated a very large fortune. For eighteen years he was Lay Judge of the Court of Errors and Appeals at Trenton, N. J. His death was caused by cancer.

MARRIAGES.

COE—WERDEN.—In New Haven, by the Rev. Jos. T. Duryea, D.D., of Boston, Dr. Harry C. Coe and Miss Sara Werden.

REED—BEAZELL.—July 20th, 1882, by Rev. Geo. MacDonald, John W. Reed, M.D., and Miss Mary M. Beazell, all of Beallsville, Monroe county, O.

VAN DEUSEN—HAPPER.—At the house of the bride's mother, Mrs. Sarah Happer, in Albany, Ill., August 16th, 1882, by Rev. Thomas Galt, of Aurora, Ill., Dr. Robert Van Deusen and Miss S. Belle Happer, both of Albany, Ill.

WILDMAN—COLLIS.—In this city, on the 9th of August, 1882, by the Rev. Charles Citcateri, Dr. Wm. Wildman and Miss Lizzie Collis, youngest daughter of the late Wm. Collis.

DEATHS.

BUDD.—At his residence, in Mount Holly, N. J., on August 14th, 1882, A. E. Budd, M.D.

REYNOLDS.—At the residence of his uncle, Mr. Daniel H. Brooks, at Port Chester, N. Y., on Friday morning, August 18th, Dr. James B. Reynolds.

SUMNER.—Suddenly, in Brooklyn, on Thursday, August 31st, 1882, Albert E. Sumner, M.D., in the 42d year of his age.

TOMES.—August 28th, at his residence, No. 502 Cleason avenue, Brooklyn, Robert Tomes, M.D., in the 66th year of his age.

WALES.—On August 19th, at Tuckahoe, N. J., Dr. E. L. B. Wales, aged 77 years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

FŒTAL MEDICATION.

BY T. CURTIS SMITH, M.D.,
Of Aurora, Ind.

That the normal status of the fœtus in utero and its continued viability to the date of its birth depends largely on the normal condition of the mother's life fluid—the blood—needs no argument at my hands. It is a well known fact. Not only do we know any dyscrasia affecting either parent may, and often does, leave its ugly impress on the fœtus, but also that it may even destroy its life. We know that infants have been brought forth with the variolous pustule already well advanced in development. The fearful loss of fœtal life because of maternal contamination with syphilis while pregnant is not less an established fact. It is not less well known that some forms of acute infectious and inflammatory diseases cause the death of the fœtus in utero, and lead to abortion or miscarriage. Notably, variola and pneumonia produce this result in the pregnant woman, especially so if well advanced in her term. All these and other well recognized clinical observations in this connection need only to be mentioned—they are long well recognized facts.

Not less is it well known that the fœtus is sustained in its viability, is nourished and acquires its material for growth, up to the time for the commencement of independent existence, from the blood of the mother. Not that there is a direct vascular connection with the arteries and veins of the mother. But the osmotic principle gives a connection sufficiently close to admit of free passage of the circulating medium from the mother to the fœtus and return. That this occurs rapidly will be demonstrated further on, and has been many times proven by experimentation. Have we taken sufficient note of this fact from a practical point of view? Have we considered that we may medicate the fœtus at will through the medium of the mother's blood? It is true that medical men have, and do now, make some use of this knowledge; but may we not widen the field, and by doing so add much to the comfort of the mother in some instances, and much to the chances of the continued viability of the fœtus as well as to its future health prospects.

If a pregnant female comes to us with the statement that she has had several abortions or miscarriages, and is now anxious to bring forth a living child, we deem it to be our duty to carefully treat the case. We inquire into her history and also that of her husband. We may not always find some marked dyscrasia present in either of them, but generally we shall find evidences of syphilitic contamination or of a morbid condition that prevents continued fœtal viability to the end of the term of pregnancy. If the blighting cause is a specific poison, then antispecific remedies are demanded. There is no need for me to refer to the many cases already given in medical literature, to show that a pregnant syphilitic woman may be so treated as to bring forth a seemingly healthy child, though many failures may have fallen to her lot before specific treatment was instituted in favor of fœtal viability. True, it is easy to ask, "May

she not, in this instance, have brought forth a seemingly healthy child?" No one can positively say yes or no. But clinical experience has proven that the chances of continued fœtal viability under these circumstances are far greater when anti-specific treatment is persistently used then when it is not.

Other causes than syphilis may produce the death of the ovum, as insufficient placental respiration, anæmia, etc. These can be met as the special cases may require.

Some years ago I treated a young man for primary, indurated chancre. After the ulcer was healed, but before secondary lesions were manifested, he married a fine, healthy girl. He did not ask advice as to whether it was best to unite in wedlock with one who was pure and innocent. In less than a year his wife came to me with a well marked syphilitic eruption, and gave a clear history of vulval sores. She had inguinal and post-cervical adenitis, sore throat, etc. She was placed on anti-syphilitic remedies. In three months more she came, with evidences of conception, and a few marks of constitutional syphilis still visible. The condition of the husband was that of a marked syphilitic. He had been all too indifferent to his situation and advice concerning his case. By persistent efforts I kept the mother on her anti-syphilitic agents. At term she was delivered of a large, healthy looking boy. No marks of contamination were present then, but within a few months there was undoubted evidences presented by the infant, to show that it had not fully escaped the baneful poison. Under treatment, however, it grew and thrived quite well. How much influence the treatment had in this case I cannot say, but the results were, I think, very good, considering the untoward conditions under which this child was conceived and delivered.

In another similar case that came under my care about the same time, all the clinical circumstances being quite exactly the same, the woman refused regular and persistent treatment. She was treated for about six weeks during the early months of pregnancy. The fœtus was thrown off during the eighth month, a mass of decomposition, and the mother was a great sufferer from syphilitic lesions that had remained practically without any treatment for months.

Mrs. V. came to my office in 1870, saying that she had had five successive abortions and was again pregnant. I did not recognize any syphilitic marks in her case at that time, though it was one where such contamination was to be expected. I afterwards learned that her husband had suffered from syphilis before marriage. The woman was thin, anæmic, feeble, run down. I placed her on the persistent use of tincture ferri chloridi, with hydrarg. bichloridi. As she was anxious to be delivered of a living child at term, she was readily induced to take the remedies. She went to full term, for the first time, and gave birth to a seemingly healthy, male infant. After that she had four or five pregnancies, all successful. She took the same treatment during the second successful pregnancy as the first, but not after that. She was often weak and anæmic during those years, and I often added anti-syphilitic agents to ferruginous tonics prescribed for her. She had several times showed undoubted evidences of constitutional syphilis. Here was a case where success crowned efforts in the interest of fœtal viability in a marked degree. True, no one can say that she would not have carried the sixth conception to its full term, but the inference can but be very strong that she would not have done so without proper treatment.

Other and unrecognized causes than those above named are often at work blighting the fruit of the womb. Perhaps every physician of considerable experience has met with instances where both the husband and wife seemed to be entirely healthy. Yet about the close of the fifth to the seventh month, or at most, the eighth, the fœtus would die and a still-birth would be the result. No perceptible cause is known. No recognized dyscrasia is present. Under these circumstances I do not believe we need to stand utterly powerless in all cases. If there is not sufficient placental respiration to maintain the viability of the fœtus, we should resort to the use of those agents that will aid in giving the needed respiratory power, or so far change the blood of the mother as that fœtal life may be sustained to the close of the pregnant term.

Simpson advocated the use of the "alkaline salts for facilitating placental respiration in instances of morbid placenta." Of this plan, Prof. Reamy, of Cincinnati, says he believes it "is of more scientific value than is generally believed by the profession (*Obstet. Gaz.* May, 1882, p. 240.)

Dr. Thrush, of Cincinnati (*loc. cit.*), in discussing this point says, "Two premature births had taken place in two successive pregnancies, the one at five and the other at seven months' gestation, intra-uterine death of the fœtus, from fatty degeneration of the placenta, being manifestly the cause of the premature delivery in the second pregnancy. No special constitutional vice was discernible in either husband or wife. This lady,

in her third pregnancy was placed simply upon a systematic course of chlorate of potash, as recommended by the late Prof. Simpson, together with suitable hygienic precautions; the result being that the respective labor occurred at the normal end of utero-gestation, and terminated in the birth of a fully developed, vigorous child."

In cases of this kind, Mr. Grinsdale, of London, claims success with chlorate of potash in a number of cases; not where a constitutional vice is present, but where there is diseased placenta or other reason present why the fœtus was rendered non-viable.

If chlorate of potash has such power as to add to respiratory ability of the placenta, or to so far change the maternal blood, and add to its alimental powers for the fœtus as to render better the chance of continued fœtal viability, may we not have other agents equally good? May not the tinct. ferri chlor., as given in the case of Mrs. V., have had a like effect, as well as that of enriching the blood of the patient. Very able men have advocated this very use of the tincture of iron, and have given as glowing accounts of its utility as have the followers of the plan advocated by the late Prof. Simpson. As the circulation by osmosis, at least, going on between mother and fœtus, is sufficiently free, why should not proper remedies properly used have such influences as are here ascribed to them?

Rhigini has noted that iodoform, when administered to the pregnant woman, is soon to be found in the liquor amnii. Dr. Kubasson (*Compend. Medical Science*) has, by using the microphone, observed the effects, on the heart of the fœtus, of medicines taken by the mother.

1. Chloroform and chloral hydrate he finds have first a stimulant and then a sedative effect on the fœtus, this last effect being evidenced by the dullness and infrequency of the heart's beat, and the greater quietness of the fœtus. They act within five or ten minutes, chloral more powerfully than chloroform, and especially so if given per rectum.

2. Opium and its alkaloids cause prolonged irregularity of the heart's beat in the fœtus, acting more slowly but for a longer period than chloral or chloroform. Opium acts more powerfully per os than per rectum.

3 Digitalis has also a powerful and prolonged action on the fœtus. Dr. Kubasson believes, from chemical examination, that a dose of chloral-hydrate taken by the mother is divided, within fifteen minutes, between herself and her fœtus, in proportion to their respective weights. The practical conclusion is that a dose of more than thirty grains of chloral hydrate will be dangerous to the child if given at once, per rectum, or repeated sooner than in half an hour. The same holds good for one and a half grains of opium in tincture repeated sooner than in an hour. (*Medical Press and Circular.*)

If these statements of Simpson, Rhigini, Kubasson and others are true, they can certainly be made of practical utility in many cases in practice, not only to combat the syphilitic dyscrasia, so destructive to fœtal life, and not only in cases of any other recognized dyscrasia, or of fatty degeneration of the placenta, but also in many cases where fœtal movements, from their violence and long continuance, cause great distress and even the threatening of premature delivery. A little clinical personal experience in this connection may illustrate at least one of the ways in which this knowledge may be used with great advantage and comfort to the patient, and no loss of credit to ourselves. In 1866 my attention was called by a lady in her eighth month of gestation to the very strong movements of the fœtus. She said there were times when it was quiet enough for her comfort. But also there were whole nights that she could not sleep or get any rest, on account of its incessant movements, and at times the pain caused by its motions was difficult to endure, on account of their severity. Placing the hand over the abdomen I found its gyrations were to be distinctly felt, and their force and strength were surprising. Being asked to prescribe I was somewhat puzzled. This was a new form of difficulty, undescribed in books or by teachers, as far as I then knew. And my then limited experience in obstetric practice led me to doubt whether I should attempt to do anything. However, as the uterine irritation was quite marked, and the pains were not altogether unlike those leading to miscarriage, I concluded to give her a tolerably full dose of opium. I did not expect to quiet the fœtus, but to allay, in some measure, the irritability of the uterus and control the pain, and so render its movements more bearable. In less than an hour the pain had entirely subsided. But it was also noted that the little uterine inhabitant was as quiet as a sleeping baby at midnight. This effect I thought might be simply accidental. The lady, however, was instructed to repeat the dose of opium only when a repetition of forcible movements seemed to bring on distressing pain or to cause threatened miscarriage. On inquiry, a few weeks later, I found that she had several times resorted to the anodyne powders, and they never failed, not only to relieve the pain, but to also

quiet the fœtus and check his forcible gyrations. From that date to the present, quite a large number of similar cases have come under my notice, and very many times have I resorted to this practice with quite uniformly good results in giving relief to the pregnant woman. No known or discovered injury has resulted to the fœtus from this practice.

Mrs. L. called on me in her eighth month of gestation, third pregnancy. She was having very severe uterine pains, and the character of them might easily have misled one to suppose she was suffering from colic. A close investigation of the cause of the pain led to the discovery that the fœtus was in violent agitation, and its incessant motions seemed to cause the pain, and the pain was proportionate to the force of its movements. I gave her a full anodyne. In less than an hour the pain was all gone, and the fœtus was also very quiet. She had several repetitions of this experience, but the suffering always ceased when the fœtus became quiet, and one full anodyne dose always gave the needed relief.

I will refer to one case more, as a fair type of quite a number with which I have met in obstetric practice.

In June, 1881, I was hastily called to see a young, stout, married lady. She was hale and hearty, a primipara, that had enjoyed the best of health. She stated that she did not think her time was up for a month or more, but might be mistaken. On examination I found the neck of the uterus very little, if in any extent, obliterated, being, as yet, quite its normal length, and no sign whatever of the beginning of real labor. But I further at once noted that the little uterine occupant was kicking around his narrow apartment at a furious rate, and that the pain was proportionate to these fœtal gyrations. If the fœtus became quiet for a time, there was a complete cessation of uterine pain, and when the little uterine occupant would again commence his furious motions, the pains instantly returned, with proportionate severity. I told the lady that I judged her time for delivery would not be out for perhaps two months, and that the false alarm and pain now endured was induced by the movements of the fœtus. I gave her a full anodyne, waited an hour, and all became quiet. The fœtus had ceased his summersaults, and no further pain was present to distress the lady or alarm her friends concerning a miscarriage. She was not confined for nine weeks after that date, but had several times to resort to the anodyne for relief from the pain caused by the fœtal movements. There was no occasion for the use of the anodyne, nor any pain present at any time, except that seemingly caused by her very restless uterine occupant.

This is but one of a large number of similar cases coming under my notice, and which I have managed in this way with quite uniform success, as to the relief afforded to the mother and producing quiet of the fœtus. I think these instances show clearly that the fœtus may be medicated with quite a fair degree of success, and that when its remedial needs are known we may often meet them with a tolerable degree of promptness and certainty. Moreover it has been my experience that most of the so-called "false alarms" of labor, that so annoy and provoke both the pregnant woman and her attendants, are caused by fœtal movements, and that the pains cease whenever the little uterine inhabitant is made quiet by any anodyne or hypnotic. I certainly also have attended cases of labor where the uterus was opening its mouth, and all seemed ready for delivery, and yet not a pain would be felt, only as the fœtus would move forcibly. It is easy to quiet the fœtus, if deemed best, but it may not be always wise to do so in such a case.

No injury has resulted to the fœtus from this treatment in my hands, though one can easily see that fatal results might follow too large or frequently repeated doses of any powerful anodyne.

The fear of establishing the opium habit is quite groundless. In no case coming within my experience in this line of practice have I had occasion to give more than six or eight doses of any anodyne, and as this number of doses is stretched over a space of from one to two months, the doses being generally one to two weeks apart, it will at once be seen that any dangers of establishing the opium habit are quite at a minimum.

From what has been stated we think we may conclude—

1st. If we may depend on the results of the experiments of Rhigini and Kubasson, that remedial agents given to the pregnant woman will promptly affect the fœtus, and the effects will be proportionate to the dose.

2d. The fœtus of a syphilitic mother may have its chances of continued viability greatly increased by proper anti-syphilitic treatment persistently used during pregnancy.

3d. Any recognized dyscrasia of the mother that is likely to destroy the fœtus may be often met and fœtal viability secured to the end of the term of pregnancy, by administering the remedies to the mother.

4th. In cases of fatty degeneration of the placenta or other placental disease, the continued

viability of the fœtus may be secured by sending to it better blood, *i. e.*, by enriching the mother's blood, or increasing the power of placental respiration, through the use of the alkaline salts, iron, etc.

5th. The movements of the fœtus may be promptly governed by administering anodynes to the mother in fairly full doses.

6th. The internal administration of any powerful therapeutic agent may lead to the death of the fœtus, and hence, to abortion or miscarriage.

IS MEDICINE A SCIENCE?

BY A. H. CARRIGAN, M.D.,

Of Washington, Ark.

Read before the Hempstead County (Ark.) Medical Society.

I was stopped on our streets not long ago, by Judge John R. Eakin, of the Supreme Court, and Judge A. B. Williams, of our Circuit Court, and asked the question, "Is medicine a science?"

Judge Eakin had informed me previously that Judge McClure, of Little Rock, had made an address before a literary society of that city, in which he took the position that medicine was an empiricism and not a science. Hence the following remarks:—

The term science is very hard to define. We speak of a scientific work; it may be a mechanical structure, a book, a painting, or any other thing done in accordance with known principles. Science literally means something that is known, or to know; then is medicine something that is known, or is it an empiricism? This is the question we propose to discuss. Empiricism means to pretend to know something that we do not know.

Let us try the rule, and see how it will work. All well informed physicians agree on the knowledge of human anatomy. Name a bone, a muscle, a ligament, a vein, or an artery, and every well informed physician in the world will be able to lay his hand on it. They agree further, viz., as to what are the functions of these organs, tissues and structures, as far as is known. Now, anatomy is one of the branches of medicine and a science; not a completed one, but, perhaps, more nearly completed than any of the branches of medicine.

Physiology is another branch of medicine, which teaches the laws of life, from the simplest cell to man, the highest type of organzied being, as manifested in health; and pathology teaches the laws governing the same structures in a diseased state. These laws are known and acknowledged by all well informed physicians of every school. Many of these laws are demonstrable, and the others as much so as the laws of gravitation, which all scientific men acknowledge to be true. No man can demonstrate what life is, yet no sane man would deny that life is. Then we say these laws of life in health and in disease are known and uniform, and that all well informed physicians know and acknowledge them to be so. Is physiology a science or an empiricism?

Materia medica is a branch of medicine, or rather it is a history of the origin, composition and effect of the agents with which physicians combat disease. This embraces a knowledge of botany, chemistry, pharmacy and therapeutics. The first three are exact sciences and capable of demonstration. The last, therapeutics, is where the greatest irrationalism does exist and has existed in all the past. It is in this branch of medicine that quacks and patent medicine venders find the widest field to ply their calling; and it is not to be wondered at that they exert an influence upon the ignorant masses, by placing their almanac medical lore freely in the hands of every man; but from the better informed classes, such as lawyers, ministers, and newspaper editors, we should expect better things. But the compounders of this patent, vicious stuff, that floods our land, and their blatant, brazen agents, that are found in every nook and corner of our country, with brush and paint, publishing their own and their masters' infamy on every pine log, whitewashed wall and fence, these are the miserable ghouls that are robbing the afflicted among the ignorant poor of our land, and giving them worse than nothing in return. And when we ask the powers that be to paralyze their hands, by compelling them to place upon their box or package the name and quantity of each medical agent that enters into these wonderful compounds, we are too often refused, with some unkind remark.

But it is of the better informed classes that we propose to speak more at length. It is by these classes that we are too often sneered at and called empirics, because we fail in one of the branches of our learned profession, forgetting the fact that in the very nature of things, it is impossible to always be exact or even to approximate a demonstration.

Even in this, nearly all well informed physicians agree, as to the use of remedies; and by the practice of vivisection we are enabled to use on the lower animals the great advances made in chemistry and pharmacy, and to perfect our knowledge in regard to the great number of remedies that we already have. And even in this,

those pseudo-philanthropists are doing all they can to prevent us from using the lower animals for the perfection and advancement of our knowledge in this respect.

They say therapeutics is not a science, and when we attempt to make it, as far as possible, a demonstrable science, they throw every obstacle in our way, and then cry out "empiric."

The other branches of medicine, viz., surgery and obstetrics, are now demonstrable, or our knowledge of the principal surgical operations are known as soon as named, by all well informed physicians, which necessarily makes it a science. The same is true in regard to all obstetric procedures.

People that live in glass houses ought not to throw stones. Is law a science? Let us apply the same rule to lawyers that we do to ourselves. Is law a science? One has said that law was the science of the decisions of the judges. The ancient judges are represented as blind, holding the scales equally balanced, which would indicate that they would weigh out equal justice to all parties.

Such might have been the case in primitive times, but such is not the case now. We see our judges in the highest courts of our country often giving a majority and a minority decision on the same subject, the majority ruling. Is the law then a science, or is it an empiricism? Or the law may be well enough, but the judges may be corrupt; which is it? Take the practice of our lawyers in the common courts of our country, and what do we see? One side or the other evidently doing their best to defeat the objects of justice. In this case the law is the science of doing right and the science of doing wrong, the science of virtue and the science of corruption, the science of doing justice to our fellow-men, and the science of defeating the objects of justice, for lawyers have to know how to do all these things, none of which are expected at the hands of an honorable physician.

Is theology a science? We think not, since one sect teach one thing, and another teaches another thing. To say the least, its teachings are not as uniformly held by its teachers as the scientific principles of medicine. Theology, like therapeutics, cannot be demonstrated, but its teachings can be illustrated in the lives of Christian men and women, which class form the highest type of our civilization, yet its teachers can and sometimes do put on the livery of Heaven to serve the devil in, especially when they underwrite for patent medicine humbugs.

The knowledge of theology is not as universally agreed upon as the knowledge of medicine, by its teachers. Truth is capable of being demonstrated from every standpoint, by all just theories bearing upon it, but many things that we believe and practice, and teach, must, in the nature of things, ever remain only theories, in regard to which, if we can neither believe nor accept them, nor advance a better one on the same subject, self respect would indicate that we had better say nothing.

What shall we say of the editors of our newspapers? We would remark that the press is the power behind the throne, in all civilized lands; it is not the axe or the hammer, the forge or the steam engine, the plow or the hoe, the weapons of warfare or the soldiers that use them: but it is more than all these. It shapes the opinions of the unthinking masses, as well as those that think. It comes to us in our moments of idleness, and we read, it may be but a paragraph; that paragraph may arouse a train of thought that will result in a succession of deeds that may bless or blight the condition of thousands.

Should such a power be used for improper purposes? we think not. But let us see how it is used sometimes. Take up any weekly or daily paper, and you will see some such editorial remark as this: "Black Drop always cures chills." "Everybody uses St. Jacob's Oil." Now all well informed editors know that such statements are not true; and I must say, that a majority of our editors are well informed; yet all will bear witness to the fact, that thousands of such statements can be seen in the newspapers of the day, endorsing and recommending just such patent stuff as we have indicated above. Are the fees these editors get for such statements better than life and health? Surely, they think so, or they would not make them, or they sell false opinions very cheaply, for their opinions, in most instances, sell the stuff to the unthinking masses; and that strangest of cranks in the "human brain, the potency of secrecy," comes to their help with the better informed people, and they are enabled to impose upon them. Thus the editors of our papers inveigle the masses into buying every vicious compound that is thrown upon the market, provided always that the vender has the *money* to pay for such notoriety and the ingenuity to keep anything out of his stuff that will kill at once.

Then, what sort of a science is editing a newspaper? It is the science of all sorts of power, both good and bad.

Let us notice a few things that modern scientific medicine has done for the race in the last

few years, and let these facts answer the question as to whether medicine is a science or an empiricism. The hypodermic syringe is an invention of scientific medical men, by which, when the stomach cannot retain anything, we can soothe and calm the tortured victims of pain, and reach the brain with proper medicines when all the usual approaches are blocked against us. The aspirator is another instrument by which we can safely penetrate any organ or cavity of the body and take away any septic fluids which, if left alone, would in many instances produce death; and Esmarch's bandage, by which we now, in many instances, have a bloodless as well as a painless surgery. Those of us who have racked our brains over the uncertainty of the pulse, know what a blessing the discovery and application of the fever thermometer is, not only to the physician, but to his patients also; and the microscope, by which the educated physician is enabled to understand the nature and cause of many diseases that were formerly as sealed books; also many crimes are brought to light, which without it would never be known. These are a few of the many instruments that modern scientific medicine has brought into requisition to clear up the misty uncertainty of the past, and I would ask any candid, capable observer, have they done it? During the past winter, when smallpox, like a loathsome demon, threatened all parts of our fair land, how many doubted whether vaccination would protect or not? In this field modern chemists have recently cultivated a virus that has been successful in arresting two diseases in the lower animals that always proved fatal to them. These recent discoveries are big with promise to the human race, since by their use we hope and believe, in the near future, to be able to arrest many, if not all, the epidemics that sweep over our land. "Physiological inquiries are pointing out to us the right direction of our therapeutic measures, and lighting up areas to be never successfully illuminated by empiricism." For instance, nitrite of amyl in angina pectoris, hydrate of chloral as a hypnotic, digitalis to furnish compensatory power to a diseased heart, and iodide of potassium to sweep the blood in certain specific diseases; and in jaborandi, or its active principle pilocarpia, with which we can wash the blood of its impurities, even if the patient is unable to swallow; and if some of those flippant, discourteous gentlemen that sometimes practice in our courts would allow us to inject some of this medicine under their skin, we think it would convince them that we understood the science of both making them sweat and spit. But I think I have said enough to convince the most skeptical that medicine is not only a science, but a living, aggressive science, with greater probabilities of brilliant achievements in the future, than in any other department of human effort. When we look at ourselves and others around us, in our daily routine duties, making no advances in scientific discovery, barely keeping up and using the advances made by others, we often become discouraged; but even this unwelcome picture that some of us have to hold up as our life work, has a silver lining, for we belong to a profession which has done, in this our age, for itself, that which no other learned profession in America has done for itself, viz., compelled the respect, admiration and patronage of Europe.

We hardly know what to say or think of any one who still persists in saying medicine is not a science, with all the achievements of the third quarter of the nineteenth century beaming upon them with more than electric brightness, unless they belong to that class described by the poet, when he says—

> "When in sickness, if not before,
> God and the doctor we adore;
> But in health both are alike requited;
> God is forgotten and the doctor slighted."

SCHOOL HYGIENE.

BY T. J. HOPPEL, M.D.

An abstract of an address read before the West Tennessee Normal Institute.

The teacher should study the manner in which his room is lighted. The want of a proper amount of light, and the faulty direction from which the light is admitted, is a frequent cause of myopia, or, discarding technicalities, of short-sightedness. An examination of the eyes of school children and college students, made by Dr. Priestly Smith, showed "five per cent. of school children under thirteen years of age, and twenty per cent. of college students, affected by short-sightedness." Dr. Ware, of England, in a paper read half a century ago, before the Royal Society of London, established the fact that "short-sightedness was much more prevalent among the educated than the illiterate. Cohn, of Breslau, has made more extended research into the matter than any one else, and from his report we find, "in the elementary school 6.7 per cent., in the intermediate school 10.3 per cent., in the high school 19.7 per cent., and in colleges 26.2 per cent. of the pupils affected with the disease in a greater or less degree." "After a full course in the high school, 50 per cent. of the first class, and

in colleges 55 per cent. of those finishing their education, were short-sighted."

Dr Loring, of New York, seriously discusses the question as to whether the human eye, under modern education, is changing from its normal state and becoming myopic.

The Ophthalmological Section of the International Medical Congress, held in Geneva, in 1877, voted its belief in the two following propositions, among others:—

"1st. The ordinary causes of myopia (near-sightedness), are heredity and eye work, the influences of which may be separate or combined."

"2d. The progress of civilization, and particularly of school education, tends to increase the extension of myopia."

The labors of all the different writers upon the subject have conclusively shown a direct connection between the disease and improper or excessive study under imperfect illumination. Teachers, directors, and parents have an interest in school hygiene pertaining to this important question. You see many of the present generation early in life wearing glasses. Not all of these are near-sighted. Some wear glasses because they need them, some because it is fashionable. If you can, in your school room, so manage as to lessen the number of those who are compelled to wear glasses, you decrease the list of those who wear them for other causes. How can you, as teachers, parents, or friends, remedy this evil? Much depends upon the faulty way in which the school rooms are lighted; and, of course, then, much can be done, by way of relief, by knowing the evil and as far as in your power removing it. An insufficient light is a great evil, but an improper light may prove a worse one. A careful study of the subject has shown that school rooms should be lighted from the pupils' side, preferably the left, if possible, and that the windows should occupy an area in the wall equal to at least one fifth of the floor space. If not enough light can be gotten from the left of the room, then admit it, if possible, from the right side; but by no means from the front, or, unless compelled to do so, from the rear. If from the front, the glare of the light is so great as to damage the eye; if from behind, many of the rays are cut off by the child's head; if from the right side, a few of the rays are lost, in right-handed children, by the way in which they ordinarily hold their books; or to express the idea a little differently, the eye should always receive the reflected rays, not the direct ones. To favor the eye still further, windows should be curtained, and those school books should be selected in which the paper is smooth, white, and the type large and distinct. The study of the pupil should be carried on, as much as possible, by daylight; the use of artificial light should be avoided.

Further, if, when you take charge of a new school, you find the light admitted into the school room at a disadvantage, not in accord with scientific investigation, you can so arrange the desks and seats in the room as to remedy the evil to a great extent. Again, the proper slope of the lid of the desk materially aids vision. A book or slate on a level surface cannot be used by a pupil without his or her leaning forward in a constrained position, deleterious both to vision and the respiratory organs. The leaning forward produces a congestion of the whole visual apparatus, resulting in short-sightedness.

The proper inclination of the desk lid for reading or any kind of study is an angle of about 40° or 45°; for writing, not more than 20°. You can demonstrate this fact by having a child with a normal eye read from a book held to suit the eye, and you will find the angle formed by the book so held with a horizontal line, to be about 40° or 45°. Follow nature in these matters. She is generally correct. A movable desk lid, to fix at 20° for writing and 45° for other purposes, would be a desideratum in our school rooms.

A proper relationship between the seats and desks should also exist. The old straight-back bench belongs to the age of the Inquisition, and has long been discarded; but the opposite extreme must be guarded against. From careful research and examination, it has been demonstrated that the front edge of the seat should be in a perpendicular line with the posterior edge of the desk, and should be a little higher in front than behind! while the back, after inclining slightly forward in the lower sixth, should then bend back only a few degrees from the perpendicular. Desks and seats should be adapted to the age and stature of the children in the school room.

The bones of children differ materially, in their component parts from those of adults. There is an excess of animal matter in the bones of children, making them softer and more flexible than those of adults; hence the necessity, in addition to the demands of vision, for a perfectly adapted seat. You, then, are to see that your school is so seated as to best conform to the facts demonstrated, as stated above, in reference to the effects of light upon the visual apparatus, and then to see that your pupils avail themselves of light properly

admitted, by retaining proper positions at their desks, correcting at all times any errors that they may fall into, so as to prevent the contraction of bad habits in these matters, which soon become a second nature. Many cases of near-sightedness have been contracted from the vicious habit of holding the book so close to the face as to prevent the teacher from observing any mischief which the pupil may be doing.

Hospital Reports.

UNIVERSITY OF THE CITY OF NEW YORK.

CLINIC BY ALFRED C. POST, M.D.,

Pofessor Emeritus of Clinical Surgery.

Cervical Adenitis.

Gentlemen:—This boy, aged nine years, complains of a swollen neck. It is a case of cervical adenitis, an inflammation of the lymphatic glands of the neck, which has gone on to suppuration at this point. I observe, in addition to that, there is a little preternatural fullness in the region of the thyroid body. It is more conspicuous than it usually is, and yet the enlargement is not so great as to be of much importance at the present time, unless it has a tendency to grow. You are aware that the thyroid body is frequently the seat of chronic enlargement or hypertrophy, which is known by the name of bronchocele or goitre, and it presents itself under several different forms, sometimes occurring as a sporadic disease; that is, an individual case occurring here and there, without any special connection with each other; and at other times it appears as an endemic; that is, in certain localities, you find a very considerable portion of the population affected with it. Those localities where bronchocele or goitre occurs in the endemic form are usually deep, shady valleys in mountainous regions, as among the Alps in Switzerland and Savoy, among the hills of Devonshire, etc. This endemic form of the disease, when it occurs in the Valley of Savoy, is frequently associated with a very imperfect cerebral development, and the associated conditions is called cretinism, and the person affected with the disease is called a cretin. In these cases we have an enormous enlargement of the thyroid body, with a very imperfect development of the head. The brain is very small and the stature is dwarf, the ordinary height of a person so affected not exceeding about four feet. In the deepest parts of these valleys a very large proportion of the people are thus affected, the cases differing from the sporadic form, of which the present case seems to be particularly a slight one.

There is a form, however, of bronchocele different from both of those which I have mentioned, and which is known as exophthalmic goitre. In this you have, at the same time with the enlargement of the thyroid body, also a protrusion of the eyeballs, and certain associated nervous symptoms. It is quite a formidable disease. It struck me, on looking at this boy, that his eyes were remarkably full, and it is quite possible that this may be a case of the incipient stage of exophthalmic goitre. I do not pretend to say that it is so, yet; the symptoms are not sufficiently well marked to make one positive, but there evidently is a slight enlargement of the thyroid body, and his eyes are somewhat preternaturally prominent.

You may remember that, some weeks ago, there was a case here somewhat like this one, so far as the cervical adenitis is concerned, in which there was quite a collection of pus, and in which I made a puncture and evacuated the matter, and injected the sack with a solution of carbolic acid, one to forty. This is known as Collender's treatment, sometimes called collendering the disease—distending the walls of the sack with dilute carbolic acid for the purpose of destroying any germs that might exist there, and favoring the healing of the abscess. It is well known that when, without any antiseptic precautions, an abscess is opened, so that air is admitted into its cavity, a certain amount of decomposition takes place, the discharge becomes more or less offensive to the smell, some symptoms of blood poisoning may manifest themselves, according to the extent of the abscess and the imperfect manner in which the matter is drawn off. These unpleasant consequences are guarded against very much by collendering the abscess; that is, by making an opening of moderate size and distending the abscess with dilute carbolic acid, about one to forty; under varying circumstances it may be from one to twenty, or one to fifty. From one to thirty to one to forty is the strength generally used. When the abscess is a large one, some precaution should be used, so that no considerable quantity of the carbolic acid shall remain behind, to produce toxical effects upon the blood. There are cases on record in which not simply a slight ill effect, but a fatal result occurred from injecting too much carbolic acid into an abscess or other cavity. If a considerable quantity of the acid be absorbed, it produces a very depressing effect upon the system, and it may even prove fatal. But in the case of an abscess of this size it is perfectly safe, even if you inject a stronger solution than that mentioned.

Restoration of Divided Nerves.

Case 2.—This man, about twenty years of age, has a scar upon the anterior part of the right forearm, three or four centimeters from the wrist joint, and extending more than half way across the palmar surface of the forearm. The injury which gave rise to this scar occurred about nine months ago, and was caused by a piece of glass. When the hand is thrust through a pane of glass it is very apt to divide the arteries of the anterior part of the wrist. You have there the radial artery, which is on the outer or radial side of the flexor carpo radialis; and very often the ulnar artery, lying on the radial side of the flexor carpo ulnaris, also is wounded, and sometimes there is an intermediate artery wounded, which is known as the median artery, an artery which accompanies the median nerve, which in many persons is lost in the forearm, but in some is nearly as large as the radial or ulnar. Thus, sometimes, three arteries require to be ligated in an accident of this kind. As a general rule, where these

arteries are divided, it is best to tie both the proximal and the distal end. This patient does not know whether these arteries require to be tied or not, but the probability is, judging from the course of the scar, the radial artery was injured; the ulnar may have escaped. You will recall the anatomical distribution of the nerves of sensation upon the palmar surface of the fingers. You will remember that the index finger, the middle finger, and the radial side of the ring finger, receive their nerve supply chiefly from a branch of the median nerve; while the ulnar side of the ring finger and both sides of the little finger derive their nerve supply from the ulnar nerve. Now, it is very evident, from the fact that there is more greatly impaired sensibility here in the index finger and middle finger, and to some extent on the radial side of the ring finger, that the median nerve has been divided, and that its function has not been perfectly restored. You know that when a nerve has been divided, and that ends are left in the wound, pretty near each other, they will reunite, and the function of the nerve, as far as the power of sensation is concerned, would be more or less perfectly restored. Unfortunately, where the nerve is divided for the relief of neuralgic pain, the healing of the parts and the restoration of function occur very much too soon for the comfort of the patient. There are a great many cases of neuralgia where division of the nerve gives relief, but after the lapse of a number of days, weeks or months, the pain returns, and that is one of the misfortunes in regard to the treatment of neuralgia by division of nerves. In order to secure persistent benefit from the operation you not only have to divide the nerve, but exsect a very considerable portion of it. Even *then* there is doubt with regard to the permanence of the cure. The impairment of sensibility and of mobility is what this patient complains of. He can bend his fingers, but he cannot bend his thumb. The probability is that the nervous supply of the muscles of the thumb has been cut off, and it has not been largely restored by anastomosis, for the anastomosis of nerves is by no means as perfect, so far as function is concerned, as is the anastomosis of arteries. You will observe that when the patient attempts to move the thumb, he moves the first phalanx of the thumb chiefly by the action of the flexor brevis, the short muscle which constitutes the upper part of the thenar eminence of the hand. That muscle has not been deprived of its muscular power, but the flexor longis pollicis has been deprived of its power, as he is unable to flex the last phalanx of the thumb.

With regard to restoring the function of divided nerves, there is a difference between the nerves of sensation and those of motion. Restoration of the function of sensation takes place to a much greater degree than that of motion. When the motor nerves have been divided there is much less chance of the patient regaining lost power of function than there is in the case of sensation. It would seem there is more active nervous power required for a nerve of motion than one of sensation; at all events, the fact, I believe, is a general one, that the restoration of motor function is much less perfect than that of sensation. As said, he cannot bend the distal phalanx of the thumb, and I fear nothing can be done to restore that lost function. If he were suffering from any intense pain we might cut down and expose the nerves at the seat of the injury, and if any bulbous expansion were found, dissect it out. We sometimes find an expansion on divided nerves, rendering them the seat of pain, and the excision of such expanded portions will often give relief, and more often give relief which will be permanent. You cannot, however, absolutely rely upon the relief being permanent. This patient does not suffer sufficiently to require such an operation.

Bone Sequestrum.
